The report establishes the following facts The ambulance arrived at the hospital as the clock was striking 2 30 P M Three minutes later the assistant resident medical officer examined the child in the admission ward , it was then wrapped in warm blankets He ordered an injection of morphia At 2 40 he described in detail to the medical superintendent the areas affected by the burns He put aside his other duties and went to the surgical ward Morphia was injected at 2 45 and the child had been removed to the surgical ward by 3, at which time the assistant resident medical officer, putting aside his other duties, went to the ward and gave the intravenous injection of blood plasma , he remained with the child till after 5 P M No complaint of delay was received until a police officer attended the hospital to take statements The report suggests that the absence of complaint gives conclusive value to the times entered in the drug book and case-record

The subcommittee had previously considered the propriety of the treatment Competent opinion was agreed that the child was suffering from severe burns and shock , that it would be bad practice to attempt to treat the burns until the child had been treated for shock , that the proper treatment was to apply warmth and to inject morphia , that, after the morphia, no further treatment must be given until there had been time (approximately 15 minutes) for the morphia to take effect, and that during this interval the child should not be moved Competent opinion advised the committee that not only was this the proper treatment to apply in the first instance but that this was the treatment in fact given After this preliminary treatment, and not before, it was desirable to give an intravenous injection of blood plasma Here also the correct treatment was given The report thus removes the adverse impression left by the inquest proceedings If it was right that the matter should be ventilated before the coroner, it is fair that the result of the hospital inquiry should also receive publicity

Counterclaims for Professional Negligence

Allegations of professional negligence are a not unfamiliar sequel or set-off to a claim for fees The practitioners to whom the fees are owed have then to consider whether the trouble of suing the defendants is worth while Allegations, however ill founded, must be rebutted , their "nuisance value" looms large to a practitioner who has other preoccupations more profitable and attractive than a day in court A successful claim for fees, on the other hand, promotes the advantage of the profession as a whole The labourer is worthy of his hire and there is no reason why he should submit to what he may regard as the process of being blackmailed out of it

In McKeag *v* Shah, a recent case in the Bath county court, the defendant was doubtless misguided rather than mischievously minded The plaintiff, a dental surgeon, sued him for a fee of half a guinea for the extraction of a tooth The defendant filed a long letter in answer and counterclaimed for £15 for alleged negligence Having read the letter, the judge told the defendant that, on his own showing, there must be judgment for the plaintiff for 10*s* 6*d* with court fees , his allegations were serious , had he, asked the judge, any professional evidence in support of them ? Mr Shah had fortified himself with no such testimony He gave his own story of the extraction , a fragment of the tooth, he said, had been left behind , there was continued bleeding and swelling afterwards, for which treatment was required Mr R K McKeag (who holds a medical as well as a dental qualification) gave evidence that it was a perfectly normal extraction , for reasons which he explained to the court there was more than ordinary bleeding in a certain percentage of cases The defendant asserted that an X-ray photograph should have been taken before probing , Mr McKeag replied that this was unnecessary The judge found for the dentist on the claim and found against the defendant on the counterclaim for damages for negligence The allegations, said the court, were entirely without foundation, ought never to have been brought, and, having been brought, ought not to have been persisted in The dentist had given sound advice and excellent treatment and had been most wise in coming to court and facing the allegations "So far from having his reputation impaired, he will, in my judgment, have established it on a higher footing" Here, at any rate, we may conclude, the trouble of suing for a fee was well worth while

VAPORISED SULPHONAMIDE IN BRONCHIECTASIS —Three Argentine physicians [1] are using a method of treatment for bronchiectasis and other forms of chronic pulmonary suppuration, which in their hands has proved highly successful in cases where ordinary medical measures have failed Inhalations of a vaporised solution of Prontosil Soluble are given thrice daily For each inhalation 3–5 c cm of the 5% solution is used, made up to 25 c cm with saline and vaporised in a special apparatus Treatment must be continued for at least three months, and each patient receives on an average a total of 50 g of prontosil soluble The only toxic effect observed has been diarrhœa, which in a few cases has been persistent enough to preclude further use of the drug In these cases Rivanol inhalations have been substituted, but this drug has an unpleasantly bitter taste The method can easily be used for ambulatory patients

In England Now

A Running Commentary by Peripatetic Correspondents

I WAS talking the other day to the former chief of the astro-enterological section of the Sanidad de Guerra—he Spanish Republican R A M C This brilliant surgeon has spent the last two years (with an interval when he was torpedoed while working in Atlantic convoy) reading he surgical literature of this country and has become an ardent admirer of the British School of proctology After so long a wait it seems almost unbelievable that his kill and that of his other colleagues may soon be at our disposal He told me about a staff routine which the Sanidad kept up even in the bitter final phases of the Republican's defeat The case-records of every wounded oldier were centralised on the desk of a specialist and so my friend received the reports of every abdominal njury These would comprise the front-line casualty ward, the operation notes dictated to the anæsthetist during the course of the first surgical intervention near the line itself, the ward notes in that same advanced urgical post, the notes made in the hospital train and the record of the base and convalescent treatment He would analyse these and send to each surgeon concerned a note of the end-result of his work together with comments given not in the form of military orders but as the advice of a senior colleague to a co-worker in a common task He did not believe in rigid standardisation of treatment, for, as he said, putting a doctor in uniform may make him keep step and salute but cannot be used as a means of depriving him of his own professional initiative and judgment Standardisation pushed to these lengths defeats its own end It would be interesting to know whether R A M C methods do permit of such coordination of surgical work

THE EGO AND THE ID

Said the Ego to the Id
"Pray tell me all you did
In the days when your subconscious fast was locked,
It would interest me vastly,
Be it ne'er so grim and ghastly,
And, let me add, I'm very rarely shocked

For myself," continued Ego,
"I early learned to leggo
And see my fancy take me where it would,
But years of self expression,
Have left me the impression
That I've always really hankered to be good"

Quoth Id "When I was five,
I used to catch alive
And torture little insects by the hour,
At six I shot my sister,
I can't pretend I've missed her,
This complex Adler calls the lust for power

I spent the next few years,
Despite my parents' tears,
Defying every code or book of rules,
My elders and my betters
Received indignant letters
Demanding my removal from five schools

Throughout my teens I joyed
In libidos dear to Freud,
The twenties saw me rush from crank to crank,
I tried out thirty diets,
I headed fifteen riots,
I broke my father's heart and broke his bank

I've dabbled since that time
In every sort of crime,
And sowed a goodly harvest of wild oats,
I've tried my hand at arson,
But since meeting with a parson,
I feel the time has come to burn my boats

By dint of free confession,
I have banished all repression,
The cupboard's bare, the skeleton is out,
No more can I pretend
When I cut my oldest friend
That I really do not know what I'm about

For I've been analysed,
And motives once disguised,
Have now, alas, become an open book,
Gone crime with all its glory,
Life's quite a different story,
The analyst has got me on a hook

So if there's anyone
Who thinks it would be fun
To talk for hours to one who's paid to listen,
Consider first the price,
And take the *free* advice
Of a wistful, erstwhile out and out Narcissan

Henceforth you must eschew
All excuses old or new,
And say farewell to irresponsibility,
Essay not to recapture
Crime's first fine careless rapture,
But concentrate on middle aged utility

Maintain a state of grace
By reflecting on the Race,
The future is to them and not to you,
Let their synthetic good
In mating or in food,
Become the theme of all you think or do

And now the least, but last,
Forget about the past,
No longing, lingering looks at childhood's horrors,
So cut the Gordian Knot,
And remember Mrs Lot,
Have done with all your Sodoms and Gomorrahs

I hope I've said enough
To deter all but the tough,
This business is no joke, please rest assured,
But if with groans and tears,
You can stick it for three years,
You can count on being killed or being cured!"

* * *

The compulsory evacuation of the London teaching hospitals has brought to the fore a problem which has worried some of us for a long time Many members of the staffs of these hospitals have a comparatively slight knowledge of educational methods, and some of them refuse to believe that there is any connexion between the teaching of clinical subjects and university education In the provinces the problem does not exist to anything like the same extent, for the medical schools there are so intimately linked with the university that they cannot help being imbued with its methods and traditions But the London teaching hospitals have led a life of proud independence Though latterly hard economic facts have made them face up to the fact that but for their grant from the University of London their very existence would be problematical they still adopt the attitude that it is the university which should be proud of its association with their ancient seats of learning

In the prewar days the organisation of the London teaching hospitals was of little practical importance and capable of a simple solution The preclinical departments were run quite efficiently as more or less independent units with their own whole-time teachers, and the clinician took little interest in them As often as not they were practically ignored and comings and goings between hospital and school were few and far between Again, so far as the clinical side of the teaching was concerned, there was little to worry about The material in the form of patients was there, the organisation in the form of the hospital authorities was there, and what little organisation seemed necessary from the point of view of the students was considered mere office routine, efficiently looked after by a dean who usually was an occupant of a chair in one of the preclinical departments Many clinicians were quite cynical about it all—no clinician of repute had time for office work, that was a job for a whole-time professor Under these circumstances teaching was little trouble to the clinician He turned up for his rounds or outpatients—part of his statutory duties as a member of the honorary staff—and his clerks or dressers accompanied him, gleaning what facts they could from the great one as he visited or examined his patients A call to the country of course took precedence, no matter how little warning it might be possible to give to the waiting students Actually they did not suffer much for there were usually juniors available to take the place of their chief With our happy faculty for evading unpleasant issues the question of conflicting loyalties as far as hospital and private practice was concerned never arose, for the latter came first

The evacuation of the hospitals and medical schools has changed all this No longer are patients, organisation or juniors supplied with unfailing regularity No longer are there alternatives to which the students can go if a round is cancelled Organisation has been necessary, planning has been indicated, awkward questions have had to be faced What constitutes a medical curriculum ? How can the absence of outpatients be compensated for by the use of inpatients ? Are medical and surgical lectures essential ? If so, how many should be given what subjects should they cover and who should deliver them ? How long should any one student spend in any one hospital ? Can students be left for, say, a term in a hospital with ample clinical material but little in the way of teaching ? The response of the average clinical teacher to this barrage can only be described as lamentable There have been notable exceptions and the picture has perhaps been overpainted, but the essentials are true enough to life to be depressing Alas that such august institutions should be so bankrupt of ideas Not only the existence of our London medical schools is involved, but the whole future of the medical curriculum If medical education is to keep pace with the progress of medical science and medical service to the community, reform must be drastic A whole-time dean, as he exists in many American medical schools, will be needed, for the organisation of a medical school can no longer be left to the whims of consultants fastened into an unstable framework by a part-time dean in his spare moments. We must produce an adequate supply of whole-time deans from among the most able members of the profession—men with experience of clinical work and research and with a flair for administration who will be prepared to give their lives to the absorbing probems of medical education As a corollary, the clinicians must realise that teaching is as important a part of their life as medical practice and that to conform to the requisite standards they will need to give a much larger part of their time, energies and abilities to the task than many of them do now

* * *

A fantastic thing happens every month or so in my area which I suppose has its counterpart in every section of the kingdom Eight or ten commercial competitors, none of whom have military interests, sit round a table to decide which among them or among other competitors not directly represented (at any rate in a voting capacity), should go into the Army Their choice is guided by the imposition of a quota, an arbitrary number of Army "vacancies" to be filled Consideration of the needs of the district does not seem to be within the competence of the meeting The picture is made all the more bizarre when you realise that these men are not only commercial competitors but also professional colleagues , they are in fact medical practitioners

Doctors by and large seem to take an individualistic view of their relations to society This is illustrated by the fractional attendances at B M A meetings, and it seems an odd anomaly of war-time planning that the health of the nation should be exposed to the voracious demands of the fighting Services transmitted through the very coarse filter of local medical war committees So far as can be seen these committees, subject to an occasional appeal to the more balanced central body, are the real and deciding factor in shaping the civilian health services It is hard to find any other principle in the adoption of this method of medical conscription except perhaps the old one of "set a thief to catch a thief" which was, after all, abandoned by the administration of Sir Robert Peel so far as it concerned the police about 100 years ago I am not suggesting that the personnel of committees do not try to be honest, but the general practitioner member is qualified neither by experience nor his own interests to make a good job of it There is no "consumer" advice to the committee, since neither local governments, public-health authorities or insurance committees have a vote

The Shakespeare Committee was said to be on tour finding out just what the medical needs of the community are If silence and inconspicuousness be a mark of efficiency its report should be good, though it does not need a committee to show that reception areas need more doctors, that public-health responsibilities increase with war, and that hospital treatment is no more efficacious to soldier patients if the doctor has got a Sam Brown belt

* * *

A minor revolution gets scant notice these days and it is not surprising that the fall of a distinguished leader and the establishment of a new order have caused no stir in the medical world The pituitary has always occupied an exalted anatomical position but in recent years it prestige in the endocrine system also has been steadily growing America's leading brain surgeon honoured it by special study and summed up his views of it importance in the famous phrase "the leader of the endocrine orchestra" And then we came to learn how "the leader" exercised control by this and that tropic factor The hormonal jigsaw puzzle was all but solved But now Dr Cramer (*Bull N Y Acad Med* 1941, 17, 3 comes along to make us start all over again The pituitary, he says, is not the leader The endocrine orchestra has no leader The members know the secret of working together and are a model for any League of Nations Their bond is simple and is based on one point, not on eight or fourteen points The One Point is the necessity of keeping the peace, or, if you prefer it in terms of physiology, of keeping the internal environment constant They know, what the human race has still to learn, that by pulling together they survive , by pulling apart they perish

SANITARY CONGRESS IN SCOTLAND

Sir Alexander Russell, M D , whom the Department of Health for Scotland has charged with the organisation of their diphtheria immunisation campaign, at the annual meeting in Glasgow of the Royal Sanitary Association of Scotland said it was ironical that the first national effort to immunise British children against diphtheria should have been postponed until the time of a world-wide war During 1940 there had been 15,711 notifications compared with an average of 10 000, and the total deaths numbered 676, the highest recorded for many years During the first quarter of 1941 the epidemic continued but there had been a steep fall in the notifications from April to June Recent weekly figures were still above average and there was reason to expect that the number of cases might shortly increase, perhaps reaching epidemic numbers during the winter Analysis of the deaths showed clearly that pre-school children were far the most susceptible, and it was disturbing that of the total immunised 60% were school-children and only 33% pre school Immunisation against diphtheria should now take a permanent place in every health officer's annual programme Sir Alexander Macgregor, M O H for Glasgow, gave a warning that the wave of incidence of diphtheria was not over He said that half the child population of Glasgow had been immunised but there was a serious need to protect the remainder of the children Dr G V T McMichael, M O H for Paisley, suggested that doctors should make it a routine practice to advocate immunisation in every home they visited He could not see how 75–80% of the children could be immunised without another intensified national propaganda campaign

Mr William Cunningham, chief sanitary inspector for Clydebank, said that before the raids they had theorised about emergency measures , in practice they found many of their pre-war deductions were wrong He was convinced that mutual help was the only way to meet the disorganisation which might be caused by attack All local authorities would do well to arrange for their public-health departments in an emergency to be augmented from the staffs of other authorities

Dr Nora Wattie, senior child welfare M O for Glasgow, had been surprised that most children had come through the bombing with so little effect But the small amount of clinical air-raid shock did not mean that no harmful influence was at work and the evacuation of children was still an urgent problem

Dr Frank Main M O H for Perth, thought that a drastic overhaul of school quarantine for infectious diseases was overdue Thousands of school attendances were unnecessarily lost each year by the exclusion of contacts, while a child with a severe cold might, and usually did, remain at school to infect the whole class

Letters to the Editor

NURSING RECONSIDERED

SIR,—Over ten years ago THE LANCET rendered a great public service in setting up a Commission on Nursing. Very little progress has been made since that commission reported because neither nurses nor their employers have been willing to face the problems involved The title of your leader "Nursing Reconsidered" gives us hope that THE LANCET is still interested in the nursing question

Many of us have worked for years on projects for a more comprehensive training for the general trained state-registered nurse We published our scheme in the *Nursing Mirror*, on which you were good enough to comment, because we had come to the conclusion that reorganisation of training would be useless unless carried out as part of a much wider plan to embrace the provision of suitable nursing care for everyone who wants it, including the old, the infirm, and the incurable—all those unfortunate people most inaccurately lumped together under the designation "chronic sick."

Looking at it from another angle we realised that there are thousands of women of all ages who could never be described as the "cream of our public school girls," many indeed who have left and are still leaving school at 14, who have a real liking for nursing and are prepared to do it, if conditions and salary scales are attractive The majority of these women have neither the aptitude, education, nor ambition to become teachers and administrators, but many have the patience, kindliness, faculty of accurate observation and practical good sense which are the marks of a good nurse We want to attract these people and give them a first-class training, and then register them and so provide the public with enough nurses

You rightly wish to protect the title of nurse, but unfortunately it is already debased, for it is given indiscriminately by private individuals and public bodies to trained and untrained alike We want to end this and to protect the public by registering every woman who makes a living at nursing and to debar from practice all the rest of the nursing miscellany In our scheme we ask for two types of nurses, Grade 1 and Grade 2, both state-registered, both well trained and excellent in quality Such a plan will not harm those state-registered nurses present and to come who can add other talents to the common store There will be ample room in the nursing profession for teachers, leaders and specialists if the public is to get all the nursing and the health teaching it needs

When the war started an Interdepartmental Committee on Nursing Services was sitting It had issued an interim report and was accumulating facts, lacking which final judgment on the needs of the nursing profession cannot be made This committee ceased working when the war started THE LANCET would do no more than seek the fruition of its own work if it could stimulate a demand for the resuscitation of the Athlone Committee

HOME GUARD PROBLEMS

SIR,—In your last issue both Mr Abel and a Peripatetic correspondent mention what to me appears as the core of the Home Guard problem—viz , the isolation which military necessity will impose on treatment As administrator of the 1st British Medical Unit to Spain I had in the first months of the Spanish war some experience of improvised hospital work in forward areas where fighting was evolving from guerrilla form towards positional warfare This leads me to stress a point neglected (or rather, in my view, misrepresented) by Mr Abel—that of *concealment* He recommends that "A large notice with the letters H G and a red cross should be exhibited in a conspicuous position" so as to mark the casualty collection point My difficulty (which would be shared by the casualties) is that this distinctive marking would be available to the enemy, who would have a local air superiority in order to be engaging the Home Guard at all Facing the same opponents in Spain we had to discard all red cross markings, even brassards, as experience showed us that they invited priority of attack by aircraft artillery and sharpshooters

Apart from this criticism, which in no way affects the main argument, Mr Abel's communication demonstrates very clearly that the period during which the Home Guard was considered to be unique amongst fighting units anticipating a casualty rôle of nil (or was it annihilation ?) is now ended As Mr Abel points out, casualties may have to stay near their units, as evacuation may be a military impossibility This isolation may well continue for days or even weeks Their points of concentration then must be equipped to care for them until they can be passed further back, which means that some surgery *must* be done The scope of this work will in effect be parallel to that of a rural practice 50 years ago With the help of the district nurse staffing difficulties may be minimised , materials, under present conditions, obviously have to be "scrounged," or at any rate earmarked in advance of the emergency for transit to the point by M O (his own surgical kit), district nurse (her armamentarium) and voluntary housewife-nurses (scrounged ward kit)

On the question of nomenclature, it seems to me that the function of the Home Guard first-line casualty service indicates the title "casualty concentration point" "Casualty collecting point" is surely euphemistic if named with reference to any evacuating service and suggests that function is confined to assembly Manifestly more than this is required

K. W C SINCLAIR-LOUTIT

M O for Civil Defence, Finsbury

SANATORIUM STAFF

SIR,—Committees may come and committees may go, but a general appreciation of the present difficulties facing those engaged in the treatment of tuberculosis in this country is still long overdue The tuberculosis system of this country is not merely a useful thing to have around, it is of vital importance to the nation , this is even more evident since the advent of war At the present moment the sanatoria are not merely dealing with their usual quotas , one's clinical impression is that the number of discovered tuberculous cases is increasing, return cases are on the increase, and furthermore there is every indication that this increase will continue The actual treatment is not a matter which can be learnt out of a book, nor will the possession of a D P H give any clue to the problem , it is solely the prerogative of experience Yet at this time invaluable key personnel, and I say key personnel advisedly, are being removed from the staff of various sanatoria on the excuse that they are wanted in the Forces They are irreplaceable and surely their services are of more use to the nation in the proper place which is the sanatoria Their removal is short-sighted policy, and there can be no doubt what section of the community will eventually suffer—the general public

Royal Chest Hospital, E C 1

J A KENNEDY

SOLDIERS AT CIVILIAN V.D CLINICS

SIR,—Will you allow me to reply to the letters of Dr White and Dr Erskine in your issue of Sept 20 ?

That a man should have been diagnosed gonorrhœa by a civilian specialist and urethritis subsequently by a military specialist has done *no* harm, so far as I can see, except to the civilian specialist's amour propre If there is any known method of ensuring that some thousands of medical officers and some tens of thousands of soldiers all obey regulations—and there are regulations about filling up the pro formas—I should be glad to be informed of it The pro forma was made to fold once and be kept in the paybook , if it is filled up correctly it contains all the information necessary. There is no guarantee that a V 44, if adopted, would always be filled up correctly and always be sent with the patient when he attended a civil clinic A soldier's proficiency pay is restored from the date when his C O , acting on the recommendation of a V D specialist, considers he has regained his physical efficiency The date of his final test of cure therefore should have no effect on the loss of proficiency pay

Perhaps I did not make myself clear as regards "theorising" What I tried to convey was that it is impracticable, even forbidden, to tell civilian medical officers where a soldier (and his unit) is stationed where he is going and when This would entail a great deal of extra work and Hitler might be listening !

It is not suggested that the present scheme is perfect but it was evolved only after much thought and discussion If Army form I 1247 were sent backwards and forwards each time a man attended a civil clinic the chances of it surviving to reach the War Office, where it is reviewed, would be small If Dr Erskine will refer to my letter he will see I did not say there *are* a multiplicity of forms It must be remembered that the commercial traveller, the actor and the merchant seaman go to a clinic only when they wish Do they always attend regularly and do they never default? The soldier is *sent*, often unwillingly It is admitted that in some cases there are gaps in treatment, this is bound to occur in those cases where there are adequate military reasons why a man cannot attend A soldier suffering from V D has direct access to his M O, he merely informs a N C O that he wishes to "report sick"

If M O 's in charge of civilian V D clinics will communicate with me direct in future, or with the Army specialist who treated the case in the first instance, we shall be only too pleased to cooperate to the best of our ability, and I feel sure this method will secure better results than ventilating the matter in the press and casting aspersions on Army methods

T E Osmond,
Adviser in Venereal Disease

War Office

FATAL STINGS

Sir,—In his interesting and important account of cases of sudden death following wasp-stings Dr Dyke discusses the possible explanations of such tragedies The one he favours is, I think alone tenable—that the insect happens to puncture a vein in the dermis so that some of its venom enters the circulation directly instead of being "fixed" and destroyed by the skin I remember many years ago discussing this question with Sir Patrick Laidlaw to whom I never took a problem without receiving enlightenment or being shown a new angle from which to tackle it He agreed with me that the above explanation was the only one that covered the facts These rare cases afford another illustration of the importance of defensive reactions in the skin in protecting the organism from major disasters Brocq in his "Cliniques Dermatologiques" describes some cases in which this function of the skin is strikingly apparent Dr Dyke refers to the experiments of Arthus in which rapid death in dogs was caused by injecting bee-venom intravenously Injection of the venom intradermally, of course, merely provokes a local reaction in the skin Another example of the disaster that may follow direct penetration of the skin-barrier is afforded by the rapid development of acute streptococcal septicæmia in surgeons or in those doing autopsies after puncture-wounds as opposed to scratches

London, W 1 H W Barber

HAMMER TOE

Sir,—In times like these there is great need of a safe and simple cure for hammer toe which will permit the patient to return to duty with the minimal delay I suggest that such a cure can be obtained from removal of the proximal phalanx Wounding of the tendons must be avoided The expanded extensor tendon soon retracts and the end-result is a slightly shortened toe which retains some movement Inflammation in the bursa over the bony prominence of the hammer toe subsides after a few days, and the corn which is always present can quickly be removed by using collodion salicylicum (20%) as a corn paint No other method seems to me to need so short a time off duty and none gives so good a permanent result

Bradford Norbert Schick

JOHANN PETER FRANK

Sir,—The significance of Frank's pioneer work in the development of medical clinics and of public health in general has hardly been overlooked in Germany as completely as you suggest (*Lancet*, Sept 6, p 296) Laudatory references to him are to be found in standard handbooks of medical history—e g, Puschmann's—and in historical introductions to hygiene manuals, apart from the scholarly monographs of Rohlfs (1880), Doll (1910), and K E F Schmitz (*Veröff Med Verw* 1917, 6, 196) Frank was, moreover, honoured by medical historians of other nationalities Thus Garrison writes "His great work on public hygiene, as covering the whole of man's life from the womb to the tomb—sewerage, water-supply, even school hygiene sexual hygiene taxation of bachelors and suitable benches and meals for the children, as well as the ideal of a scientific 'medical police,' really left little for Pettenkofer and the moderns In the preventive medicine of the future, the name of Frank will loom larger with meanings, for he was himself a true modern" And quite recently Sigerist has published (*Bull Hist Med* Jan 1941) an oration by Frank, entitled The People's Misery Mother of Diseases of which he says "One hundred and fifty years have passed since Frank delivered his address A great deal has changed since then, and yet his words still sound incredibly modern"

S H Daukes

Wellcome Historical Medical Museum, N W 1

IMPETIGO CONTAGIOSA AND NEPHRITIS

Sir,—Dr Hope Simpson (*Lancet*, Sept 13, p 328) raises a point about nephritis following impetigo contagiosa which deserves comment Nephritis as a specific complication of impetigo must, he says, be very rare, whereas albuminuria and anasarca due to sensitivity to ammoniated mercury ointment is not uncommon Nephritis may at present be a rare complication of impetigo just as it is now a rare sequela of scarlet fever but there are numerous records of "impetigo-nephritis" in the literature (see the recent reviews of Silvers, S H *N Y St J Med* 1939, 39, 1093, Futcher, P H *Arch intern Med* 1940, 65, 1192) For example, R Southby and B L Stanton (*Med J Aust* 1926, 1, 127), in an inquiry about antecedent infection in 103 children with acute nephritis, found that 17 had had impetigo two to six weeks prior to admission to hospital On the other hand, sensitivity or idiosyncrasy to ammoniated mercury is, according to P Harper (*J Pediat* 1934, 5, 794), uncommon, and mercurial nephritis following its inunction must, if it occurs at all, be extremely rare, for this mercury compound, being very insoluble, is poorly absorbed

London, N W 3 Robert Cruickshank

TRAUMATIC ASPHYXIA

Sir,—Mr Grant Bonnin writing of traumatic asphyxia (Sept 20, p 333) states that no case has been reported showing petechiæ only I cannot believe that such cases are rare and suggest that they have not been reported as they are thought to be of little interest I have seen one air-raid casualty with petechiæ of the distribution characteristic of traumatic asphyxia This is the only case of which I have notes but I have seen the phenomenon in civil injuries The patient was a boy of 14, who was buried by debris in a shelter as a result of a bomb explosion I saw him 7 hours after injury He did not appear to be shocked or seriously hurt he had petechial hæmorrhages of the eyelids, brow, neck and upper part of chest None were found in the retinæ X-ray of his chest showed no abnormality, although for 2 days there were signs suggesting consolidation at the right base He did not spit blood His petechiæ faded rapidly and were gone in a week The exact nature of the injury was not determined The boy had not lost consciousness and said that he was rescued quickly

Leavesden Hospital Robin Pilcher

Sir,—The article by Mr Grant Bonnin recalls an interesting case of traumatic asphyxia which I saw 5 weeks ago A young woman had an epileptic attack and came under my care the same day She had subconjunctival hæmorrhages, "total" on the right side, but incomplete on the left Her face and neck were a vivid cyanotic hue She was wearing collar and tie at the time of the attack, and the discoloration stopped abruptly at the level of a constriction mark caused by the collar There was no discoloration below this level I was able to observe her for 3 days, during which time the high colour definitely faded, and also became rather more red than blue It is suggested that the epileptic spasm caused venous congestion with swelling of the neck, and that the tight collar then caused further congestion sufficient to produce the appearance described above the constricting band

SPLENECTOMY IN ICTERUS GRAVIS

SIR,—The paper by Hardwick and Lloyd in your issue of Sept 20 will have been read with interest by pædiatricians Recovery in this case does not justify the assumption that splenectomy is of any value in the treatment of this disease The operation was practised for a short time in the United States, but this treatment is now regarded as irrational It is generally accepted that the splenomegaly is a reaction to the disease rather than the cause In the last few years I have observed about fifty cases of erythroblastosis of which icterus gravis is the commonest clinical type Many were closely studied from the time of birth in a maternity hospital Spontaneous recovery often occurs and the recognised sequelæ are exceptional I have recorded several cases (*Trans Edinb obstetr Soc* 1939 p 63), and have since seen a number of others, in which a very active reticulocytosis and rapid rise of hæmoglobin occurred without any treatment So long as the ætiology remains obscure blood transfusion is likely to remain the therapeutic mainstay The object of blood transfusion is to maintain the hæmoglobin at a safe level until the rate of regeneration outstrips that of hæmolysis Definite blood coagulability with hæmorrhagic signs often occurs in severe cases of the disease and can be efficiently treated by the administration of vitamin K

WAR-TIME BEHAVIOUR

SIR,—The Mental Health Emergency Committee has been making an inquiry into the behaviour of children and adults under war conditions Questionnaires have been sent out to child guidance clinics, mental treatment clinics, psychiatric wards of emergency hospitals, and to psychiatric social workers in reception areas This inquiry was intended to be only a preliminary survey and before proceeding further the committee would be much interested to learn whether any similar investigations are being carried out, either by groups or by individuals, and if so would welcome opportunities of coöperation

From the School Reports

HOLLAND (LINCS)

Dr W G Booth throws some light on the cost of the school medical service in a small county The number of school-children on the roll at the end of 1940 was 10,180, and the net cost of their medical service was £5202, or 10*s* a head per annum The Board of Education grants supplied £3282 the remainder came from the rates and absorbed 2*d* out of the general elementary-education rate of 4*s*

The use of paper towels was continued in some schools, and it was hoped to extend this system throughout the county, but that is of course impossible at present In view of the increasing prevalence of scabies this is unfortunate, for the communal school towel is open to suspicion of spreading the acarus Mr C A Johnston, senior school dentist, calls attention to the very bad state of the mouths of school entrants Caries of the temporary teeth seems to be increasing in spite of the undoubted improvement in the general nutrition of children and of expectant mothers

KETTERING

The average number of children on the school registers in 1940 was 4119 and the number of received children who remained in the borough at the end of the year was 2563 The ebb and flow of the evacuated population, most of which came from London, is interesting There was a steady reduction from 2533 in January to 1434 in August, the number doubled in September, and in October reached 1397 It has not been fully realised how great is the strain of this fluctuation on billeting and education in reception areas During the year 112 children were admitted to hostels because they were unfit for billeting Of these 26 were taken home by their parents and 65 were returned to billets because they were cured Dr Cecil Hogg, in his school report, gives some information on unsatisfactory evacuees which will be useful in the future, for evacuation has given us the only chance we have ever had to find out the number of objectionable children what percentage of them can be cured and how long it will take to cure them

Infectious Disease in England and Wales

WEEK ENDED SEPT 20

Notifications —The following cases of infectious disease were notified during the week smallpox 0 , scarlet fever, 1140 , whooping-cough 2289 , diphtheria 957 , paratyphoid, 125 , typhoid, 27 , measles (excluding rubella), 612 , pneumonia (primary or influenzal), 434 , puerperal pyrexia, 134 , cerebrospinal fever, 121 , poliomyelitis, 28 , polio-encephalitis, 3 , encephalitis lethargica 6 , dysentery, 102 , ophthalmia neonatorum, 76 No case of cholera, plague or typhus fever was notified during the week

The number of civilian and service sick in the Infectious Hospitals of the London County Council on Sept 17 was 1266 , including scarlet fever, 129 diphtheria, 252 measles, 28 , whooping cough, 571 , enteritis 22 , chicken pox, 24 erysipelas, 20 , mumps, 6 poliomyelitis, 2 , dysentery, 14 , cerebrospinal fever 21 , puerperal sepsis, 12 enteric fevers 45 , german measles, 3 , malaria 1 , polio-encephalitis, 2 , other diseases (non-infectious), 44 , not yet diagnosed, 75

Deaths —In 126 great towns there were no deaths from enteric fever, 1 (0) from measles 1 (0) from scarlet fever, 14 (1) from whooping-cough, 23 (1) from diphtheria, 38 (1) from diarrhœa and enteritis under 2 years, and 8 (0) from influenza The figures in parentheses are those for London itself

Birmingham reported 9 deaths from diarrhœa There were 3 fatal cases of diphtheria at Liverpool

The number of stillbirths notified during the week was 170 (corresponding to a rate of 32 per thousand total births) including 14 in London

Obituary

ROBERT THIN

M B , LL D EDIN , F R C P E

Dr Thin who died at Stow on Sept 18 in his 81st year had spent the greater part of his professional life in general practice in Edinburgh where his energy and kindly disposition earned him the esteem and admiration of colleagues and patients For fifty years he was associated with the Royal College of Physicians, becoming president 1931–33 when the LL D Edin was conferred on him After qualifying in 1887 and working in the Royal Infirmary and Maternity Hospital he went to Vienna and Prague studying diseases of the ear nose and throat and the use of obstetrical forceps Then as assistant to Dr George Hunter of Linlithgow he lived in South Queensferry where he was assistant surgeon to the Forth Bridge works during the period of erection Later his practice became very large and he did not find much time for writing, but he recorded in the *Edinburgh Medical Journal* a study of five generations of familial cysteinuria He was a lively member of the Old Edinburgh Club and his antiquarian interest found expression in " The Old Infirmary and Earlier Hospitals " and " Medical Quacks of the Eighteenth Century," while at the request of his college he wrote biographical sketches for the portraits hung on the college walls He carried his own years lightly and continued in practice until a few weeks of his death

WILLIAM NEIL CAMPBELL

M.D EDIN , M R C P E

THE death of Dr Neil Campbell is announced from Africa where he was serving with the South African Forces Dr. Campbell graduated in Edinburgh in 1927, taking the M D in 1939 After a house appointment at the Royal Infirmary he went out to Natal and set up in practice at Durban where his ability was recognised by his election to the staff of the King Edward Hospital, Durban During his student days he was a keen angler and athlete with a good record at rugby and field athletics He leaves a widow and two young children

It is not suggested that the present scheme is perfect but it was evolved only after much thought and discussion If Army form I 1247 were sent backwards and forwards each time a man attended a civil clinic the chances of it surviving to reach the War Office, where it is reviewed, would be small If Dr Erskine will refer to my letter he will see I did not say there *are* a multiplicity of forms It must be remembered that the commercial traveller, the actor and the merchant seaman go to a clinic only when they wish Do they always attend regularly and do they never default? The soldier is *sent*, often unwillingly It is admitted that in some cases there are gaps in treatment, this is bound to occur in those cases where there are adequate military reasons why a man cannot attend A soldier suffering from V D has direct access to his M O, he merely informs a N C O that he wishes to "report sick"

If M O's in charge of civilian V D clinics will communicate with me direct in future, or with the Army specialist who treated the case in the first instance, we shall be only too pleased to cooperate to the best of our ability, and I feel sure this method will secure better results than ventilating the matter in the press and casting aspersions on Army methods

T E OSMOND
War Office Adviser in Venereal Disease

FATAL STINGS

SIR,—In his interesting and important account of cases of sudden death following wasp-stings Dr Dyke discusses the possible explanations of such tragedies The one he favours is, I think alone tenable—that the insect happens to puncture a vein in the dermis so that some of its venom enters the circulation directly instead of being "fixed" and destroyed by the skin I remember many years ago discussing this question with Sir Patrick Laidlaw to whom I never took a problem without receiving enlightenment or being shown a new angle from which to tackle it He agreed with me that the above explanation was the *only one* that covered the facts These rare cases afford another illustration of the importance of defensive reactions in the skin in protecting the organism from major disasters Brocq in his "Cliniques Dermatologiques" describes some cases in which this function of the skin is strikingly apparent Dr Dyke refers to the experiments of Arthus in which rapid death in dogs was caused by injecting bee-venom intravenously Injection of the venom intradermally, of course, merely provokes a local reaction in the skin Another example of the disaster that may follow direct penetration of the skin-barrier is afforded by the rapid development of acute streptococcal septicæmia in surgeons or in those doing autopsies after puncture-wounds as opposed to scratches

London, W 1 H W BARBER

HAMMER TOE

SIR,—In times like these there is great need of a safe and simple cure for hammer toe which will permit the patient to return to duty with the minimal delay I suggest that such a cure can be obtained from removal of the proximal phalanx Wounding of the tendons must be avoided The expanded extensor tendon soon retracts and the end-result is a slightly shortened toe which retains some movement Inflammation in the bursa over the bony prominence of the hammer toe subsides after a few days, and the corn which is always present can quickly be removed by using collodion salicylicum (20%) as a corn paint No other method seems to me to need so short a time off duty and none gives so good a permanent result

Bradford NORBERT SCHICK

JOHANN PETER FRANK

SIR,—The significance of Frank's pioneer work in the development of medical clinics and of public health in general has hardly been overlooked in Germany as completely as you suggest (*Lancet*, Sept 6, p 296) Laudatory references to him are to be found in standard handbooks of medical history—e g, Puschmann's—and in historical introductions to hygiene manuals, apart from the scholarly monographs of Rohlfs (1880), Doll (1910), and K E F Schmitz (*Veröff MedVerw* 1917, 6, 496) Frank was, moreover, honoured by medical historians of other nationalities Thus Garrison writes "His great work on public hygiene, as covering the whole of man's life from the womb to the tomb—sewerage water-supply, even school hygiene, sexual hygiene, taxation of bachelors and suitable benches and meals for the children, as well as the ideal of a scientific 'medical police,' really left little for Pettenkofer and the modern In the preventive medicine of the future, the name of Frank will loom larger with meanings, for he was himself a true modern" And quite recently Sigerist has published (*Bull Hist Med* Jan 1941) an oration by Frank, entitled The People's Misery Mother of Disease, of which he says "One hundred and fifty years have passed since Frank delivered his address A great deal has changed since then, and yet his words still sound incredibly modern"

S H DAUKES
Wellcome Historical Medical Museum, N W 1

IMPETIGO CONTAGIOSA AND NEPHRITIS

SIR,—Dr Hope Simpson (*Lancet*, Sept 13, p 328) raises a point about nephritis following impetigo contagiosa which deserves comment Nephritis as a specific complication of impetigo must, he says, be very rare, whereas albuminuria and anasarca due to sensitivity to ammoniated mercury ointment is not uncommon Nephritis may at present be a rare complication of impetigo just as it is now a rare sequela of scarlet fever but there are numerous records of "impetigo nephritis" in the literature (see the recent reviews of Silvers, S H *N Y St J Med* 1939, 39, 1093, Futcher, P H *Arch intern Med* 1940, 65, 1192) For example, R Southby and B L Stanton (*Med J Aust* 1926, 1, 127), in an inquiry about antecedent infection in 103 children with acute nephritis, found that 17 had had impetigo two to six weeks prior to admission to hospital On the other hand, sensitivity or idiosyncrasy to ammoniated mercury is, according to P Harper (*J Pediat* 1934, 5, 794) uncommon, and mercurial nephritis following its inunction must, if it occurs at all, be extremely rare, for this mercury compound, being very insoluble, is poorly absorbed

London, N W 3 ROBERT CRUICKSHANK

TRAUMATIC ASPHYXIA

SIR,—Mr Grant Bonnin writing of traumatic asphyxia (Sept 20, p 333) states that no case has been reported showing petechiæ *only* I *cannot* believe that such cases are rare and suggest that they have not been reported as they are thought to be of little interest I have seen one air-raid casualty with petechiæ of the distribution characteristic of traumatic asphyxia This is the only case of which I have notes but I have seen the phenomenon in civil injuries The patient was a boy of 14, who was buried by debris in a shelter as a result of a bomb explosion I saw him 7 hours after injury He did not appear to be shocked or seriously hurt he had petechial hæmorrhages of the eyelids, brow, neck and upper part of chest None were found in the retinæ X-ray of his chest showed no abnormality, although for 2 days there were signs suggesting consolidation at the right base He did not spit blood His petechiæ faded *rapidly and were gone in a week The exact nature* of the injury was not determined The boy had not lost consciousness and said that he was rescued quickly

Leavesden Hospital ROBIN PILCHER

SIR,—The article by Mr Grant Bonnin recalls an interesting case of traumatic asphyxia which I saw 5 weeks ago A young woman had an epileptic attack and came under my care the same day She had subconjunctival hæmorrhages, "total" on the right side, but incomplete on the left Her face and neck were a vivid cyanotic hue She was wearing collar and tie at the time of the attack, and the discoloration stopped abruptly at the level of a constriction mark caused by the collar There was no discoloration below this level I was able to observe her for 3 days, during which time the high colour definitely faded, and also became rather more red than blue It is suggested that the epileptic spasm caused venous congestion with swelling of the neck, and that the tight collar then caused further congestion sufficient to produce the appearance described above the constricting band

ABORTION RATES IN STOCKHOLM

FIGURES relating to illegally induced abortion are not easily come by in this country An analysis of 800 cases treated at the Sabbatsberg Hospital, Stockholm, from 1935 to 1937 throws light on the fundamental causes of the practice The investigation, reported by Dr G Inghe and Dr G A Jonsson,[1] showed abortion to be much commoner among unmarried than married women, as might be expected Among unmarried women the rate reaches a maximum between the ages of 25 and 30 , in married women it rises with age Figures collected from public hospitals showed that pregnancy in unmarried women resulted in birth of the child at term and eventual marriage of the parents in a third of the cases, illegitimate births in a third and abortion in a third Many cases of illegal abortion, however, do not reach hospital, and the practice is estimated to be more common than pregnancy going to term among unmarried women About a third of the 800 cases admitted to having attempted to procure abortion, usually medicinally Most of the mothers were working women earning comparatively small wages—waitresses, kitchen hands, hairdressers and shop assistants Of the married women, those with several children and coming from overcrowded houses were more numerous than those with one or two Most of them had used contraceptives, but seldom selected the most reliable or used them regularly Many of those who knew of reliable contraceptives had not used them because of distaste, or because they grudged the inconvenience About half the 800 women were married, or living as married, and most of the rest had regular sexual intercourse , intercourse was occasional in only 7% Most of the unmarried women had sought abortion on economic grounds Poverty and unemployment had delayed marriage for some and others doubted whether they would be able to support their children Nearly half feared the social criticism which birth of an illegitimate child would provoke, and two-thirds dreaded the anger of their parents Only a third of the whole series had any idea that induction of abortion was attended with risk Among the married women, 75% gave economic reasons for their action, 10% considered themselves to be too much exhausted to have more children and 40% wished to space their children , 20% feared the inheritance of some abnormality by the child, or were influenced by memories of an unhappy childhood Dr Gårdlund, in his experience of practice in Stockholm, found that requests for abortion increased year by year Some years ago he received 170–190 requests of the kind yearly, but in 1937 the figure rose to 266, in 1939 to 278, and in 1940 to 410 Among these the cases in which he could legally undertake abortion amounted to 7 or 8 a year

"WHO WALK ALONE"

Dr Perry Burgess, president of the American Leprosy Foundation, has taken the history of a young American soldier who developed leprosy after service in the Spanish-American war in the Philippines, and told it in autobiographical form (London J M Dent and Sons Pp 318 12s 6d) His reconstruction of the emotional experience of this unfortunate young man from the facts given him during many intimate years have such verisimilitude that it is difficult to credit they were not indeed his own It shows, moreover, that the author possesses that inward sight which is the mark of the true artist, and while the tale is told in factual style the psychological element is never forgotten Nine years after the young man's return from the Philippines to America he developed leprosy, and a year afterwards was sent out to the Leper Colony on the Island of Culion in the Philippines There he started another stage of his painful spiritual pilgrimage Slowly he determined to make the best of a world that had suddenly shrunk to the cramping confines of a leprosarium He made his house and garden the most beautiful in the colony and gradually became interested more and more in his fellow sufferers He organised work schemes, and received the hearty cooperation of both authorities and patients All the time he grew in spiritual stature, and his record should be put amongst the many others of those who have achieved nobility through suffering Despite the horror which leprosy, above all other diseases, seems to inspire, this book is not gloomy but vital and lively The story reveals the mind of the incurable with an uncommon vividness, and though it is a story it is authentic

---

INDEX OF FOOD INVESTIGATION —The fascicle dated March 1941 (vol 12, no 4) contains 545 items, varying from brief abstract to a mere mention of articles on every aspect of food investigation which have appeared in Empire and American journals The foreign references are few and old Food investigation has been quickened by war conditions (this issue alone reveals 650 workers) and an index to the literature is essential to codify results and prevent overlapping From H M Stationery Office 4s 6d

FINAL EXAMINATION FOR M B , CH B

Parts II and III —Hazem Barrada, Pauline M Hardcastle, Labib Ishak, L F Q Maclaine, and Margaret E Withers

Medical Honours

The following honours have lately been awarded —

O B E —Acting Wing Commander J P Huins, M R C S , and Acting Squadron Leader B C Curwood, M B Birm

D S C —Temp Surgeon Lieutenant A G Reid, M B Aberd R N V R , H M S *Mashona*

Medical Prisoners of War

The following R A M C officers have *been posted as* prisoners of war Captain A G V Aldridge, M B *Camb* , Temp Major Robert Harvey, F R C S E , Temp Major P D C Kinmont, M B Lond , and Temp Major G A W. Neill, M D Belf

War-time Nurseries

On Oct 29 the Nursery School Association of Great Britain will meet in consultation with the National Society of Day Nurseries at the Royal Institute of British Architects Lord Horder will take the chair at 10 30 A M , and other speakers who will discuss problems of establishing war-time nurseries will be Miss Florence Horsburgh, Mr J C Wrigley and Miss Zoe Puxley (Ministry of Health), Miss Greaves (Board of Education), Lady Reading (N S D N) Dr G H Hogben (M O H for Tottenham), Lady Allen of Hurtwood and Miss Freda Hawtrey (N S A) Further information may be had from the secretary of the association, 8, Endsleigh Gardens, London, W C 1

Royal Society of Medicine

A meeting of the clinical section of this society will be held at the Westminster Hospital on Friday, Oct 10, at 2 15 P M The section of orthopædics will meet at Horton Hospital, Epsom, on Oct 11, at 2 P M , when short papers will be read and there will be a demonstration of special cases

Society of Medical Officers of Health

Sir Alexander Macgregor of Glasgow has taken office as president of this society in succession to Dr F T H Wood of Bootle

London Homœopathic Hospital

On Thursday, Oct 9, at 2 30 P M , Dr Thomas Stonham will give a lecture introducing the autumn and *winter post*graduate session at this hospital From October to May, on Mondays and Thursdays, at 2 30 P M , Dr Charles Wheeler will give a course on homœopathic materia medica and therapeutics, and from October to December, on Fridays at 2 30 P M , Sir John Weir will give ten Compton Burnett lectures on homœopathic philosophy and prescribing Tutorial classes and clinical tutorials will also be held throughout the session

Queen's Nurses

During 1940 the Queen's nurses and village nurse midwives attended 85,242 confinements for which no doctor was engaged, and they also acted as maternity nurse for 36,560 cases for which doctors were engaged There are now 1530 Queen's nurses and 2782 village nurse midwives, making 4312 in all This is a decrease of 72 which is said to be due to the reorganisation of the associations and to less work in some coastal areas

ORIGINAL ARTICLES

CYSTICERCOSIS OF THE BRAIN
WITH EPILEPSY AND PAPILLŒDEMA

W E CARNEGIE DICKSON,
M D B SC EDIN , F R C P E
DIRECTOR PATHOLOGICAL DEPARTMENT, WEST END HOSPITAL FOR NERVOUS DISEASES

J D WILLIS,
M B N Z , M R C.P.
CAPTAIN, N Z M C ,
FORMERLY RESIDENT MEDICAL OFFICER AT THE HOSPITAL

SINCE the work of MacArthur[1] at Millbank, infestation of the brain and eye with the larval cysts of *Tænia solium* has been recognised as less uncommon and more important than was formerly supposed and it seems likely that infestation with tapeworm will be frequent among our forces in the Near and Middle East When previously healthy and often comparatively young soldiers, especially any who have been abroad, for example in India, have been invalided out of the service because of " epilepsy " the diagnosis in many instances has, on further investigation, proved to be an infestation with cysticerci The epileptiform fits were usually accompanied by severe and otherwise unaccountable headaches and various obscure nervous symptoms In fatal cases, sometimes as many as 300 or 400 cysts have been found in a single brain , and in these patients there has as a rule, been no definite history of any previous intestinal tapeworm-infestation Almost all the cases recorded in this country have been in soldiers, or in soldiers' families

The case which we record here gives a typical clinical history, and also illustrates several other important points upon which MacArthur lays especial emphasis, for instance, that serious cerebral symptoms supervene as a rule only when death and degeneration of the larvæ themselves have taken place , this is because the cysts then tend to swell from imbibition of fluid, and irritative phenomena supervene in and around them (fig II*b* and lower specimen in fig IV, plate)

While the parasite is still alive it becomes surrounded and shut off by a zone or capsule of thickened and proliferated glia and a varying amount of fibrous tissue ; and, unless the cysticercus is in some specially vital position in the brain, a species of symbiotic harmony between parasite and host is established, which may last for several and perhaps for many years Serious pathological results thus in many instances ensue only on and after the death of the parasites, so that attempts at killing them by drugs must as yet be regarded as ill-advised as is also the attempted surgical removal of any of the cysts in the brain, unless they are causing serious symptoms on account of their position, or, as in the present case, because the rather unusual complications of progressive papillœdema and raised intracranial pressure threaten the patient's eyesight

Since the larvæ often survive " symbiotically " for a number of years, the more active destructive and necrotic changes around them leading to the epileptiform seizures may not come on until after a considerable " latent period " If the patient does not die in the meantime, the zone of glial and fibrous-tissue sclerosis around the dead and degenerating cysticerci gradually becomes more pronounced , and calcification, beginning in the scolex itself and gradually involving the cyst-wall, tends to be produced—perhaps only after three or four years—and X-ray diagnosis may only then become possible

At this late stage in the development of the disease, the occurrence of eosinophilia in the blood is exceptional, and the specific serum-reactions are often negative If, as in the present case, cysticerci can be palpated in the subcutaneous or muscular tissues or demonstrated in radiograms, the diagnosis may be confirmed by the examination of biopsy-specimens (fig I, plate, and fig II)

CASE-RECORD

A man of 32 was admitted to hospital under Dr Neill Hobhouse on Jan 23, 1940, complaining of " fainting turns " for three years, and severe frontal and occipital headaches for a month A diagnosis of cysticercosis had been made by Dr Macdonald Critchley in 1938 The patient had been an infantryman in India from 1927 to 1933, and during that time he had a considerable amount of illness, including " dysentery " twice, threadworm infestation twice, and several attacks of " P U O " , but, as far as he himself was aware, he had never suffered from intestinal tapeworm-infestation. Previous to going to India, he had never suffered from fits of any kind, and there was no family history of epilepsy In 1937 he became a post-office employee, and three months later had his first epileptiform attack, his own description of this being " I was just walking along when suddenly everything went black and I dropped " He was unconscious for only two or three minutes and was told that he had had generalised twitching of the limbs, but no cyanosis, nor was there any incontinence of urine or biting of the tongue He had a second attack six months later, beginning with " twitching of both elbows and shoulders " In subsequent fits this twitching constituted a premonitory " aura," giving him time to lie down These attacks came on at intervals of five or six months, with freedom from any symptoms between times His last attacks—two in one day—had occurred five weeks previous to admission and began with cramp like flexion of the fingers of the left hand into the palm and pain shooting up the forearm, followed by unconsciousness, on recovery from which he found that he had temporarily lost the use of his left hand, a disability which lasted nearly a week Intermittent severe frontal headaches then supervened, shooting round the right side of the head to the occiput, with pain in the back of the neck and mistiness of vision in the right eye There was no nausea or vomiting In 1938, a tense subcutaneous nodule about $\frac{1}{2}$ in in diameter was detected at the right costal margin near the ninth costal cartilage

The patient was well nourished, intelligent and fully coöperative Two other tense and painless subcutaneous nodules about $\frac{1}{4}$ in in diameter were found in the lower thoracic region, one on each side of the vertebral column about 2 in from the midline Cranial nerves pupils of medium size, equal, central and circular , pupillary reactions normal Vision 6/12 in each eye , visual fields full Fundi (Mr Joseph Minton) showed papillœdema on both sides, + 1 5 D, with hæmorrhage and exudate around both discs There were coarse lateral nystagmoid jerks both to right and left Tongue deviated to the right when extended Other cranial nerves normal Absent upper abdominal reflexes but no other abnormal physical signs found No nodules were palpable in the limbs By Jan 26 the papillœdema had increased to 3 D in the left eye, and to 2 D in the right , it was therefore decided to perform a ventriculography to ascertain if possible the position of any block in the cerebrospinal circulation

Jan 25 Examination of blood Coagulation-time $3\frac{1}{2}$ min , bleeding-time not prolonged Red cells 4,900,000, hæmoglobin (Haldane) 90%, colour index 0 92 ; white cells 7400 (polymorphs 47 5% , lymphocytes, small 34 5%, large 10 5%, total 45% ; large monocytes 1 5% , eosinophils 6% , basiphils 0)—i e , a moderate eosinophilia, with some neutropenia and a relative lymphocytosis, a considerable proportion of the lymphocytes being of large (more immature) type

Jan 27 Lumbar puncture Pressure 300 mm of water , fluid clear and colourless Cells 29 per c mm (small lymphocytes 91%, small endothelial cells 6%, large endothelial cells 3%, polymorphs 0, red cells 0) , total protein 0 06% , globulin a faint trace in excess , Lange's colloidal gold curve, 0 1/0 1/0 1 · 1/0 0 0 0 0 0 Wassermann and Meinicke reactions in blood negative On X-ray examination of the skull, two small rounded suspicious shadows (one about the centre of the right parietal cortical region and the other just below and $\frac{3}{4}$ in to the left of the shadow of the calcified pineal) were seen in the anteroposterior view but not in the lateral In the soft parts around the pelvis and in the upper and lower limbs and neck, typical shadows of calcified cysticerci were demonstrated (fig I)

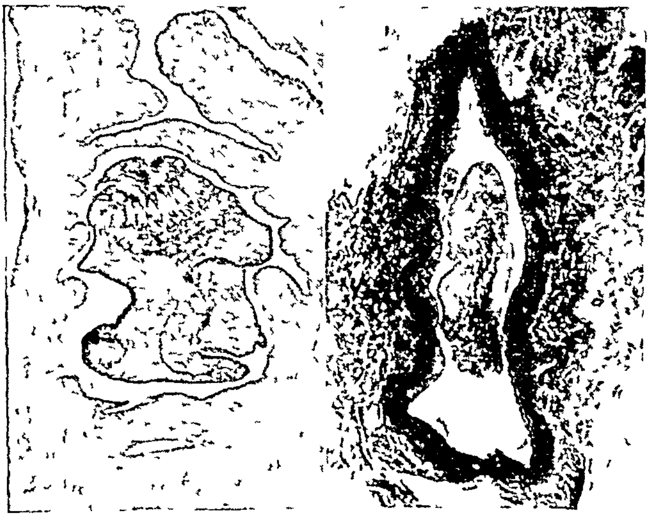
On Jan 30 a ventriculography was done, but no abnormality was detected in the ventricular system The fluid from the right lateral ventricle was clear and colourless and showed cells 1 (small lymphocyte) per c mm , total protein 0 01% , globulin no excess , Wassermann and Meinicke reactions negative , Lange's colloidal gold curve, 0 0 1/0 0 · 0 0 0 0 0 0 0

The ventriculography was followed by a right subtemporal decompression by Mr Geoffrey Knight The meninges were under considerable tension, and on opening them several small firm nodules were palpable just beneath the surface of the cortex in both the motor and sensory areas Two of these were excised for microscopical examination (fig II*b*) The patient's immediate post operative condition was good, some temporary paresis of the long finger-flexors of the left hand gradually passing off and there being no appreciable sensory changes Ten days later the papillœdema had subsided to 0 5 D in the right and 1 D in the left eye, and there was mild analgesia to pin prick and cotton-wool and two point discrimination over the left palm All of these signs gradually passed off except for flexor paresis of the left index finger On Feb 9 two subcutaneous cysticercal cysts were removed from the patient's back for biopsy (fig II*a*)

Feb 14 The patient had an epileptiform attack similar to those from which he had suffered before admission, and during the subsequent three weeks there was flaccid paralysis of, and loss of sensation over, the left hand and forearm, and several Jacksonian attacks occurred in the paralysed limb There was then rapid improvement, with return of power of movement, the cortical sensory loss being the last to recover

On April 3 the patient was discharged in excellent condition, with the decompression area well healed The optic discs were flat and showed no evidence of the previous papillœdema, vision being as on admission (R V and L V 6/12), and there were now no appreciable motor or sensory differences in the two arms

Figs II*a* and *b* are from sections of the biopsy-specimens excised from the lumbar muscles and brain respectively In fig II*a* the larva is healthy and well-preserved, but, in fig II*b*, that from the right motor cortex shows a typically degenerated dead larva enclosed in a calcified cyst, previously tensely distended, but which had ruptured and become collapsed during surgical removal For comparison with these, fig III is from a post-mortem specimen of a brain of an ex-soldier aged 28, which we owe to the kindness of Dr C Worster-Drought It shows the naked-eye appearance and distribution of the cysticerci in the brain (the right half of which was examined and in which it was estimated that there were about a hundred cysts present)[2] Fig IV, from this brain, shows in adjacent convolutions in the same section a healthy "symbiotic" cysticercus lying within its caudal vesicle or bladder, while below is a dead and disintegrating larva in a degenerated cyst which is becoming distended with fluid and the wall of which shows the development of irritative and chronic inflammatory reaction after the death of the parasite, as noted by MacArthur Details of the upper cyst are shown in fig V



a *b*

FIG II—(*a*) Biopsy specimen of cysticercus from lumbar muscles of case recorded in text Oblique section of scolex passing through two of the four suckers and base of rostellum with its armature of hooklets and its musculature Compare the well preserved structure of this undegenerated and "symbiotic" larva with the dead and degenerated parasite from the brain illustrated in (*b*) This shows one of two cysts removed from the hand area of the right motor cortex The cyst which burst and became collapsed during removal is partially calcified Mallory's connective tissue stain × 50

DISCUSSION

Attention has been drawn in several recent papers and articles[3] to the comparative frequency with which the brain is attacked in patients with cysticercosis—in different series varying from 40 to 75 or 80% of the total number The eye itself may be the site of infestation which may destroy the sight, as in Worster-Drought's case Hugh Cairns, in the discussion which followed MacArthur's paper, was of opinion that "there was no place for operative surgery in cases of multiple cysticerci of the brain," and none of the patients he had seen had anything beyond a slight degree of papillœdema "It was conceivable that there might be such cases (e g, a cyst in the precentral gyrus) in which surgery could help, but they must be rare" The case we now record appears, therefore, to be one of those rare instances in which sight was threatened by a progressive bilateral papillœdema and the raised intracranial pressure, and in which surgical interference was justified by the results obtained—the rapid disappearance of the papillœdema and the lowering of the intracranial pressure, as well as the reduction in the frequency of the fits following the subtemporal decompression

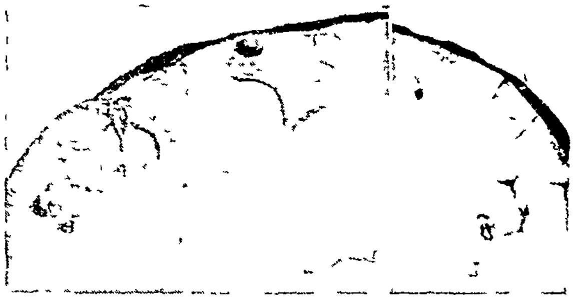


FIG III—Cysticercosis of brain of an ex soldier aged 28, who had enlisted at the age of 18 (Left) in, or just beneath, the frontal cortex are one degenerating and two well preserved cysts, whilst (right) in the occipital cortex are seen one semi degenerated and shrivelled, and two old degenerated and fibrosed, cysticerci Dr Worster Drought's case, half natural size

In his series of 61 patients with cerebral cysticercosis MacArthur mentions only one case in which any serious degree of papillœdema led to blindness some time before death, while in Dixon and Smithers's[4] review of 71 cases there were only 7 with papillœdema More recently, Gottlieb[5] described a case of cysticercosis in a girl, aged 17, with epilepsy, 2 diopters of papillœdema in both eyes, a cerebrospinal-fluid pressure in excess of 300 mm of water, and numerous calcified cysts in the brain demonstrable radiographically

As shown in fig III, most of the cysts lie within the cortex, or just beneath it, relatively few being found in the meninges or deeply within the white matter Although collectively they represent a considerable space-occupying lesion, individually they produce comparatively little interference with the cerebrospinal-fluid circulation and this is perhaps the explanation of the relative infrequency of papillœdema or of raised intracranial pressure, the occurrence of which probably indicates swelling of the brain around degenerating cysts such as that illustrated in the lower part of fig IV No evidence of hydrocephalus was found in the ventriculograms, which showed a normal ventricular system

The character of the epileptiform attacks depends largely on the site of the cysts, as well as on the occurrence of the degenerative reaction and swelling around and in the dying or dead cysticerci The symptoms sometimes produced may simulate those of acute encephalitis, disseminated sclerosis or cerebral tumour, and in some patients, with or without fits, psychical symptoms may predominate and resemble melancholia, acute mania, schizophrenia or certain less grave mental disorders

When in the subcutaneous tissues and muscles, the swellings, if numerous, may simulate von Recklinghausen's peripheral neurofibromatosis or even nodular leprosy (Greig)[4] As is well known, the cysts when in the muscles and near the surface of the body often become palpable or even visible in "crops" This is due to a sudden increase in their fluid-content following the death of the larva rather than to the development of new parasites—previously flaccid and inconspicuous cysts becoming tense and palpable It is conceivable that, in a similar way, several cysts in certain parts of the brain, particularly if situated in the vicinity of the mid-brain and below the tentorium might simultaneously become swollen and obstruct the cerebrospinal-fluid circulation and lead to raised intracranial pressure and bilateral papillœdema, without necessarily producing either hydrocephalus or ventricular distortion especially in cases seen early

The diagnosis of cysticercosis of the brain rests primarily on the occurrence of epilepsy or other cerebral symptoms usually, but not invariably, associated with palpable subcutaneous and intramuscular nodules and a history of residence abroad particularly in India It is confirmed by X-ray appearances and by biopsy when possible. The radiographical appearances are extremely variable, depending on the degree of calcification which may have developed—the brain being usually the last place in which calcification begins Skin-reactions and complement-fixation tests have not so far proved reliable guides The presence of eosinophilia is suggestive in the earlier stages of infestation but is inconstant or absent later One great advantage of a correct diagnosis is the removal of the fear of hereditary transmission and the stigma of idiopathic epilepsy, in soldiers it does away with the difficulty of obtaining a pension, for the infestation may usually be regarded as a consequence of their military service abroad

The prognosis, though serious is not, as has commonly been thought, uniformly bad In a small proportion of cases—5 in Dixon and Smithers s 71 patients—the fits ceased after a variable period A decompression operation is justifiable and desirable where, as in the present case there is raised intracranial pressure and papillœdema; and, in the absence of contra-indications, a right subtemporal decompression serves this purpose

SUMMARY

A case of *Cysticercus cellulosæ* infestation with focal epilepsy is described, in which there were the unusual features of grossly raised intracranial pressure and rapidly increasing papillœdema with a normal ventriculogram

The ventricular fluid was normal, the lumbar-puncture fluid showed a moderate increase of mononuclear cells, protein and globulin, but no polymorphs or eosinophils

The papillœdema quickly subsided after a right subtemporal decompression which also reduced the frequency of the fits

Cases of cysticercosis may be more common now that there are large numbers of British troops in the East

Raised intracranial pressure and papillœdema usually arise from swelling of the brain around degenerating cysts and are indications for decompression.

Diagnosis is made on the development of epilepsy after residence abroad (especially in India) the presence of subcutaneous nodules and the X-ray and biopsy findings Eosinophilia in the blood is of diagnostic value mainly in the earlier stages of the infestation.

The fits sometimes cease spontaneously

We wish to thank Dr Neill Hobhouse and Surgeon Captain Macdonald Critchley for putting their clinical notes of the case at our disposal Dr Worster-Drought for the specimens from his case; Mr C Martin, Mr R Egan and Miss M L Wilson for preparing the pathological material, and Mr A York, assistant radiologist at the hospital, for the radiograms

SILICOSIS IN STOURBRIDGE FIRECLAY MINERS

SIDNEY DEANER, M R C S.
CHIEF TUBERCULOSIS OFFICER, WORCESTERSHIRE COUNTY COUNCIL

STOURBRIDGE fireclay miners have not previously been recognised as exposed to a silica risk and hitherto silicosis has not been observed in such miners The investigations here recorded have established the diagnosis of silicosis in three of these workers

Clays are naturally occurring materials composed of silicates, chiefly of aluminium usually mixed with an indefinite amount of sand and other minerals The term "fireclay" is commonly applied to the more refractory clays found in the geological formations known as the Coal Measures Such clays are found as a rule beneath coal seams, so that workers in these collieries often work in both the coal and the fireclay seams In the Stourbridge area, where firebricks have been manufactured since 1780 or earlier, the fireclay is found in the "Old Mine" seams of the South Staffordshire coal measures Immediately above the fireclay in geological formation is a shale called Baxton; the rock below is a "mottled clay," a form of crude sandstone The Baxton has often to be removed to reach the fireclay. In dealing with the fireclay, the miners make their shot holes with machine drills either in the fireclay rock itself or in the mottled clay. When the shot has been fired, buckets of water are poured over the fireclay to allay the dust and moisten the clay before it is picked and collected In addition to fireclay mining, the workers in this colliery have worked in the coal seams on occasional shifts when required

The composition of fireclays varies in the same coalfield The basic constituents are shown in the following analyses which are extracted from Searle s "Refractory Materials"

	Stourbridge Old Mine	
	Best selected (%)	Ordinary (%)
Silica	76 5	56 6
Alumina	16 5	26 5
Iron oxides	0 8	2 3
Lime	0 1	0 2
Magnesia	trace	0 3
Potash and soda	0 7	1 7

Fireclay in which the contained silica is as above, in the form of silicates is "pure" fireclay, and as such does not constitute a free silica risk. The fireclay in which the three miners investigated have worked has hitherto been regarded as a pure fireclay. However, a sample of this fireclay was kindly examined under the petrological microscope for me by W R Jones, D Sc of the Imperial College of Science and Technology, and his report is as follows

> "The sections of the coarser and more coherent lumps of this fireclay show the presence of many grains of quartz, and, in parts, fibres of sericite are fairly numerous Dried fireclay of this kind could, in my opinion, give rise to harmful dust"

In addition, the following figures show the amounts of total and free silica in Baxton mottled clay, and samples of dust taken from the floors of the fireclay mine

	Total SiO_2	Free SiO_2
Baxton	42 6	7 2
Mottled clay	68 2	36 1
Dust from floors	49 6	16 2

The occupational aspect of the problem may require further investigation, but it is evident that the miners are exposed to dust from fireclay containing quartz grains, and that they are also working with a mottled clay which contains a substantial amount of free silica

CASE 1

The first patient has died and the autopsy report is included

First seen at the tuberculosis dispensary on May 23, 1934, when aged 47 Had been a coalminer for 5 years from 1906–11, and had then worked for 23 years as a "pure" fireclay miner in the same colliery, returning to work in the coal seams on occasional shifts when required Complained of chronic cough with sputum for years, dyspnœa on exertion for several months, and pains in right side of chest Previous attacks of right sided pleurisy in 1930 and 1931

Low standard of physique, general condition poor Chest expansion restricted particularly on right side Percussion slightly impaired over right apex Breath sounds poor generally, generalised rhonchi Clinically condition appeared to be due to chronic bronchitis and emphysema To eliminate possibility of pulmonary tuberculosis radiogram was taken March 29, but film revealed appearances consistent with early pneumoconiosis Decided to watch future course, radiological examinations being repeated at intervals Advised to give up colliery work Clinically remained much the same until February, 1936, when dyspnœa became worse, physical signs did not alter much apart from increasing impairment of percussion over both upper lobes Possibility of tuberculous infection was always borne in mind, but numerous sputum tests, as well as guineapig inoculation, always negative General condition gradually deteriorated, dyspnœa, aggravated by repeated attacks of acute bronchitis, being main symptom In February, 1941, seven years after ceasing work, he died suddenly

Radiological examinations—Serial films reveal a striking and progressive fibrosis, and appear to present three stages

Stage 1 In fig III*a* (plate), taken in 1934, configuration of chest is normal, heart and mediastinum normal, root shadows do not appear enlarged, well marked increase of striation with mottling throughout lower two-thirds of both lungs, most towards bases Dr A Meiklejohn, who kindly saw the film at the time, stated that "in many ways the picture is consistent with silicosis as seen in certain branches of the pottery industry There is one striking anomaly—the distribution is chiefly confined to the lower parts of the lungs as in asbestosis, whereas silicosis is usually almost identical in distribution with tubercle"

Stage 2 Fig III*b*, taken in 1935, reveals denser shadows becoming more confluent in mid-zones of both lungs and in right upper lobe Increasing translucency at bases, indicating emphysematous changes

Stage 3 Fig III*c*, taken in 1940, shows large dense opacities in mid zones and right upper lobe Basal appearances suggest "ballooning"

Despite cessation of exposure to dust, condition was progressive The evidence of emphysema appears to increase with density of shadows denoting fibrosis Later films appear to suggest infective type of silicosis, but tuberculosis was conspicuously absent as will be seen later in pathological report

Post mortem report (Dr W Stewart of Worcester)—Body rather emaciated and subcutaneous œdema present in lower limbs Left lung completely free from chest wall except for very few apical adhesions Right lung more densely adherent to pleura in upper and middle lobes, adhesions could only be broken down with difficulty No free fluid Pericardium normal but external surface showed considerable pigmentation with carbon, myocardium flabby and chambers dilated Myocardium showed increased fatty infiltration, coronary arteries affected by slight atheromatous changes No valvular lesion Liver showed well-marked nutmeg changes, other abdominal organs normal

Left lung weighed 800 g (normal 570), voluminous and deeply pigmented with carbon Upper lobe showed considerable thickening of pleura and much old scarring Large emphysematous bullæ present, largest being size of golf ball Scattered throughout lung tissue were small fibrous nodules but not so abundant as in typical silicosis Lower half of lobe coal black and composed of dense fibroid tissue containing very little air No discrete nodules of fibrosis made out in this mass, pleural thickening more pronounced over this area Fairly dense interlobar adhesions Lower lobe showed similar pleural thickening, emphysema, particularly on diaphragmatic surface, most pronounced, bullæ being size of small Jaffa orange Upper part of this lobe also showed fibrosed area with similar deep carbon pigmentation No evidence of tuberculosis Hilar glands enlarged to size of small beans

Right lung weighed 960 g (normal 625), appearance similar to left but pleura showed more thickening Upper lobe voluminous, most of lobe, except about lower third anteriorly, solid mass of old fibrous tissue and very deeply pigmented Scattered small fibrous nodules also present Middle lobe fairly densely fused to upper and lower lobes and completely fibrotic Lower lobe not quite so solid except at upper pole Emphysema very advanced In deeper substance of all lobes small bronchiectatic cavities slightly smaller than pea No macroscopic tuberculosis obvious

Bronchi showed chronic bronchitis with increased vascularity in walls

Histological examination—*Right lung* Upper lobe extremely heavy impregnation with dust particles obscured tissue appearances, considerable fibrosis of laminated whorled type enmeshing dust particles, lung alveoli having completely disappeared in fibrous mass, arterial walls considerably thickened Lower lobe patchy areas of deep pigmentation, lung alveoli distended and walls thinned, considerable engorgement of vessels, silicotic and anthracotic fibrosis present *Left lung* Upper lobe deep pigmentation, patchy in type and somewhat intensified around blood vessels, considerable pigment in lymphatic channels, silicotic fibrotic nodules present Lower lobe in solid portion appearances similar to those in other lobes, but silicotic fibrosis more definite

The pulmonary lesion is, therefore, one of chronic fibrosis, in the production of which both silica and coal dust appear to have played a part, it thus conforms to the type of pulmonary fibrosis described as silico anthracosis

Chemical analysis of portions of dried lung was made as a matter of interest

	Total SiO_2 (%)
Right upper lobe	4 9
Right lower lobe	3 9
Left upper lobe	2 2
Left lower lobe	2 2

The silica content of normal lungs is up to 0 2% on the weight of dried lung The lungs therefore contained increased amount of silica in the tissues Stewart (1933), however, found that an abnormal silica content in lung tissue cannot be taken as corroborative evidence of silicosis King and Belt (1940) also found no evidence of a direct association between the concentration of silica and the degree of fibrosis, but pointed out that in silicotic lungs silica was always in excess of 0 2%

The two other cases to be described are still alive but very much incapacitated (See cases 2 and 3 on p 419)

LEGENDS TO ILLUSTRATIVE PLATE

Man of 56 who has been a clayminer, in same colliery as first case, for past 36 years. Has also been required to work at coal on occasional shifts. Chronic cough with sputum for some years. Attacks of dry pleurisy on right side of chest in 1937 and in January, 1939. Increasing dyspnœa on exertion for past 3 years, with gradual loss of weight during the past year. Gave up work on July 19, 1940.

Low standard of physique and general condition poor. Chest movement restricted, particularly on right side. Percussion note impaired over both apices, but very few adventitious sounds heard. Had been admitted to sanatorium as case of pulmonary tuberculosis. Sputum tests, culture, and guineapig inoculation all negative for tuberculosis.

Radiological examination (fig I) shows slight tracheal deviation to right. Heart normal. Root shadows not enlarged. Distribution of lesion definitely in mid zones. On right side dense irregular opacity, rather soft in appearance, tending to spread slightly into upper and lower zones; clear area near root suggests patch of emphysema rather than breaking down. On left small irregular opacities with mottling in mid zone, not so confluent as on right.

CASE 3

Man of 63, brother of case 2. Worked in same mine as two previous cases as clayminer for 45 years. Conditions of work similar. Cough with sputum for past 3–5 years, with increasing dyspnœa and loss of weight. Early in 1940 had been off work because of pleurisy in right side of chest. Ceased work finally on July 10, 1940 because of further pain on that side and extreme weakness.

Poor physique and general condition very poor. Restricted chest movement. Percussion note impaired over both upper lobes. Crepitations over both apices, right more than left; diminished air-entry at bases. So far, sputum tests negative for tubercle bacilli.

Radiological examination (fig II).—Ribs on right side more sloping than left. Tracheal deviation to right. Mediastinal shadow widened; right side of heart enlarged. Root shadows not enlarged. On right dense opacity in the upper zone and irregular opacity in mid zone; emphysematous changes at base. On left opacities in mid-zone, with mottling towards base.

Cases 2 and 3 have since applied to the Silicosis Medical Board and have received certificates of disablement by reason of silicosis.

DIAGNOSIS

The International Conference on Silicosis in 1938 defined the disease as “a pathological condition of the lungs due to the inhalation of silicon dioxide,” the silica being in a free or uncombined state. During life, the diagnosis depends essentially on

1. An occupational history revealing sufficient exposure to a silica risk.
2. Radiological findings.
3. Clinical examination.

In an industry presenting a well-established occupational silica risk, where in a large number of cases careful correlation has already been made between the radiological appearances and the pathological findings, the diagnosis in a given case is relatively easy when clinical and X-ray findings are suggestive. Where, however, a silica risk has yet to be proved, during life only a tentative diagnosis is possible even with extensive radiological experience of silicosis in other industries. This was the position when the first case in this series was seen in 1934. The autopsy and histological findings described above now establish the condition as silico-anthracosis, and it is therefore now possible to review the criteria of diagnosis in these cases.

Occupational history, and exposure to silica risk.—That the rock at which these men have worked can no longer be regarded as pure fireclay has been shown by the demonstration of the presence of quartz grains; the adjacent rocks also contain free silica. But it is difficult to account for the intense pigmentation with carbon as seen post mortem, for there does not seem to be sufficient exposure to coal dust. It has been suggested by Cummins and Sladden (1930) that anthracosis requires for its development preceding damage of the lung by silica. Had the men worked for an appreciable time in the coalmine it might be suggested that the primary risk causing silico-anthracosis lay there, but there appears no doubt that most of their time has been spent at the fireclay. This aspect of the occupational problem requires further investigation. Our main concern, however, has been to show that the men are exposed to a free silica risk, a criterion necessary for the diagnosis of silicosis.

2. *Radiological findings*.—The series of films in case 1 illustrate the progression from reticulo-mottling to coalescence and final dense fibrosis. The initial basal distribution is unusual: it suggests the predominance of interstitial fibrosis associated with silicosis due to mixed dusts as against the nodulation seen in pure silica inhalation. The films of the two other cases represent the advancing stages of coalescence; the appearances are not so well defined as in the first case, and the infective element strongly suggests itself. The distribution is, characteristically, mid-zone. It is to be noted that the root shadows are not abnormally enlarged.

3. *Clinical history and examination*.—Poor physique and cough with sputum were noted in each case, but dyspnœa on exertion was the main symptom. Pain was also a well-marked feature, probably associated with the formation of adhesions. The loss of weight in the last two cases may arise from an infective element, especially as they are brothers, although so far tubercle bacilli have not been found in the sputum. Physical signs in the first case suggested chronic bronchitis and emphysema; in the second case they were indefinite; in the third they were suggestive of tuberculosis. It will be seen, therefore, that the clinical history and examination is typical of silicosis, but the diagnosis cannot be based on clinical examination alone, although this is essential in assessing incapacity.

* * *

It seems reasonable to suggest that these clayminers should benefit from the provisions made for the compensation of silicosis. It is possible that they are already covered by the Various Industries (Silicosis) Scheme 1931.

LEGENDS TO ILLUSTRATIVE PLATE

DR O'REILLY AND DR GLOYNE

FIG I—Case 2, within 12 hours of injury. Heavy mottling of whole left lung field and right mid zone.

FIG. II—Case 3, about 48 hours after injury. Heavy mottling of both lung fields. Consolidation at right base.

FIG III—Case 4, about 30 hours after injury. Heavy mottling of left lung field; less on right.

FIG IV—Case 5, small pneumothorax at left base with mottling of left lung field.

FIG V—Case 6, 24 hours after injury. Characteristic mottling of both lung fields, but less than in previous cases.

FIG VI—Case 7, 54 hours after injury. Collapse of right base. Subsequent films showed re-expansion and resolution.

DR ALSTEAD

FIG III—Immediately after barium meal, showing penetrating ulcer on lesser curvature.

FIG IV—Taken 2 min. after gr 30 of bismuth carbonate. Pool in most dependent part of stomach; trace adhering to mucosa of body of stomach.

FIG V—Taken 27 min after meal of toast and milk and 2 min after taking gr 30 of bismuth carbonate. Showing dispersal of bismuth carbonate among stomach contents; bulk of salt still in middle of body of stomach.

FIG VI—Taken 1½ hours later. Stomach emptying; remaining bismuth carbonate has collected at most dependent part of stomach; none elsewhere.

FIG VII—Residue of bismuth carbonate after 28 hours. Previous barium meal had shown normal emptying time.

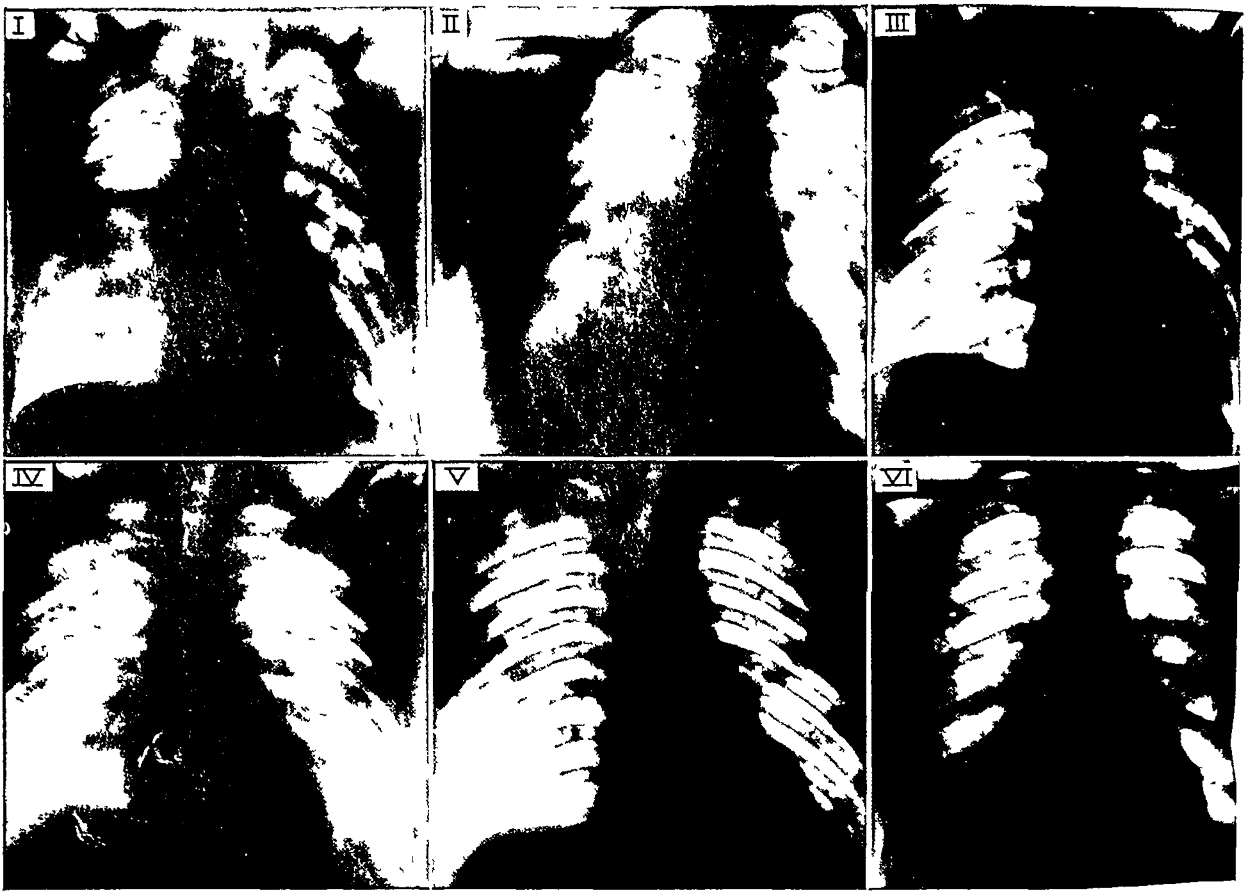
DR CLARK

FIG I—Radiogram on first attendance (March 2, 1939), showing large opaque area in left upper zone, with smaller opacity near root.

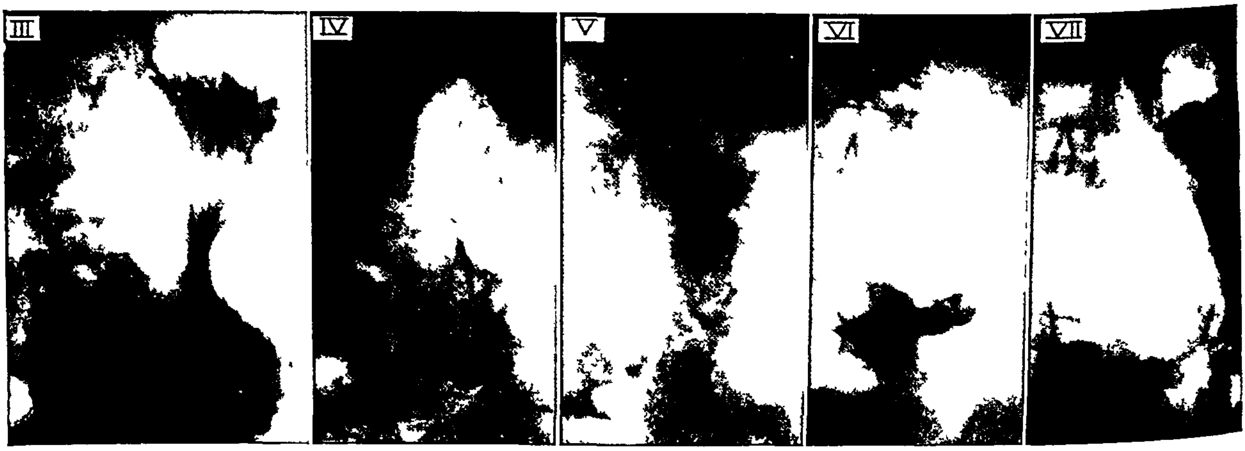
FIG II—Radiogram on April 20, 1939, showing considerable absorption of opacities.

FIG III—Radiogram on Jan 20, 1941, showing still further improvement.

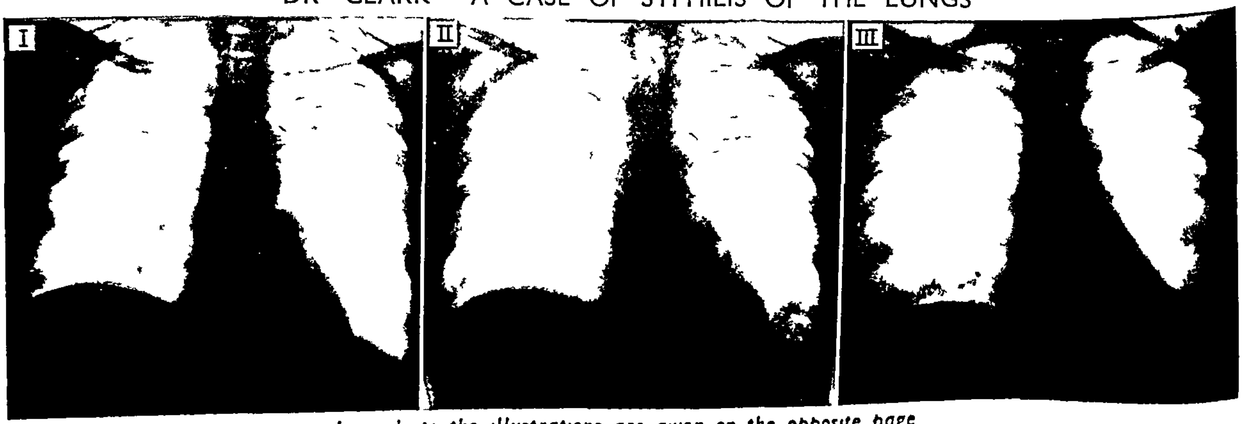
DR O'REILLY AND DR GLOYNE BLAST INJURY OF THE LUNGS



DR ALSTEAD BISMUTH CARBONATE IN GASTRIC DISEASE



DR CLARK A CASE OF SYPHILIS OF THE LUNGS



Legends to the illustrations are given on the opposite page lusting powder soothes an irritated skin Hurst (1929), nowever describing a series of radiological observations made by his collaborator Dr P J Briggs, states that "half an ounce of bismuth oxycarbonate taken in suspension on an empty stomach does not as a rule adhere to the ulcer crater surface of even a large gastric or duodenal ulcer" Bismuth carbonate is also reputed to have an astringent action on the stomach (Adams 1939), and to act as a weak antacid (Dilling 1940, Whitla 1933) The antacid value of bismuth carbonate has been carefully studied by Freezer, Gibson and Matthews (1928) They have shown that when 0 3% hydrochloric acid (pH 1) is mixed with an excess of bismuth carbonate the solution never attains neutrality, but remains persistently acid (pH 4), and no further reaction takes place after one minute They also tabulate their conclusions regarding the relative efficiency of the "alkalis" expressed as a comparison with sodium bicarbonate, which is assigned an arbitrary value of 100, the figures for magnesium oxide calcium carbonate and bismuth carbonate are 317, 20 and zero Again Clark (1940) points out that the acidity of the gastric juice secreted by a normal person in 24 hours corresponds to about 5 g of pure hydrochloric acid, and whereas this is neutralised by 3 g (gr 45) of magnesia, as much as 136 g (gr 2000) of bismuth carbonate would be required

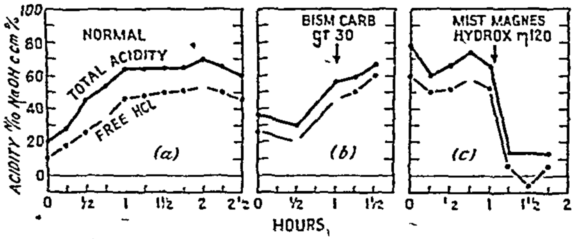


FIG I—Consecutive fractional test meals from one patient (a) Normal record (b) With bismuth carbonate 30 gr acidity continues to rise (c) With mist magnes hydrox ♏ 120 there is a large immediate fall in acidity

PRESENT INVESTIGATION

The object of this investigation was to determine the value of bismuth carbonate in relieving the pain of gastroduodenal disease, and to examine the views commonly accepted as to the fate of this salt in the stomach

Antacid action —The in-vitro experiments of Freezer, Gibson and Matthews referred to show that, although the addition of bismuth carbonate to weak hydrochloric acid raises the pH the reaction of the mixture never approaches neutrality My own observations were made using open test-tubes instead of the closed apparatus described by these workers, but the results were substantially the same A quantity of bismuth carbonate (B P) weighing 1 5 g was shaken up in a wide tube with 15 c cm of distilled water, and 15 c cm of N/10 hydrochloric acid (pH 1) was then added The mixture was filtered and the pH of the filtrate was found to be in the region of 3 3 The same result was obtained when similar mixtures had been allowed to stand for intervals ranging from 1 to 10 minutes Hydrogen-ion concentration was determined by means of chemical indicators and the Lovibond comparator and the figures are regarded as being only approximate These rough estimations of the neutralising power of bismuth carbonate on decinormal HCl were carried out merely as a preliminary to similar observations on gastric juice It was found that the addition of an excess of bismuth carbonate to gastric juice in vitro produced only slight changes in acidity, as is shown by the following example —

	Decinormal HCl c cm %		
	FreeHCl	Total acidity	pH
Before addition of bism carb	40	55	2
After excess bism carb	32	50	2 1

The feebleness of the antacid action on gastric juice is probably partly due to the buffering effect of mucoprotein

The third method of investigation consisted in making observations during fractional test-meals In any individual, however, day to day variations in fractional test-meal results are so considerable that experiments of this type necessarily lack controls that are completely satisfactory The nearest approach to obtaining adequate control readings consists in using the first three or four of a series prior to the administration of the drug under investigation Although this method is imperfect its value is increased when applied to a drug whose potentialities are already known from in-vitro experiments, and the negative results from bismuth carbonate are more convincing when compared with the effect of the powerful antacid magnesium hydroxide (fig I) In all, 9 patients were investigated by means of fractional test-meals, using half-drachm doses of bismuth carbonate It was found that the acidity was unchanged or continued to increase in 7 In 2 who had very low acidity (corresponding to 10 and 20 c cm N/10 NaOH% respectively) the curves fell to zero after the administration of the salt, that these falls were spontaneous rather than the effect of the bismuth carbonate is suggested by the fact that the addition of an excess of bismuth carbonate to gastric juice in vitro never reduced the acidity by more than 10 c cm N/10 HCl%

The effect of administering a single large dose of bismuth carbonate was also studied Two fractional test-meals were performed on a healthy medical student During the first he received an average dose (gr 15) It will be seen (fig IIa) that the fall in the gastric acidity was negligible, indeed the curves reveal that spontaneous alterations were greater than the change attributed to the action of the bismuth carbonate On another occasion he was persuaded to take a very large dose (gr 210) The effect on the gastric acidity was more impressive (fig IIb) but it lasted only half an hour My colleague Mr J B Pettigrew estimated the hydrogen-ion concentration of the samples electrometrically and found that the change was comparatively small (pH 1 67 to pH 2 16) The bismuth carbonate and bismuth oxychloride which were present in all the samples of gastric juice appeared to have caused the mucus to form curd-like masses

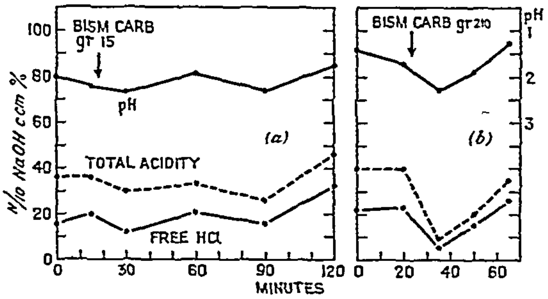

FIG II—Consecutive fractional test meals from one patient showing effect of (a) gr 15 and (b) gr 210 of bismuth carbonate on gastric acidity

Astringent action —Bismuth carbonate can act as an astringent in the stomach only if it is sufficiently soluble in the gastric juice Dissolved bismuth can be detected by adding to it a freshly prepared solution of stannous chloride in strong caustic soda, the bismuth salt is immediately reduced and is precipitated as metallic bismuth, which gives colours ranging from jet black to light brown according to the quantity of the metal present The test is sufficiently sensitive to detect 1 part of bismuth in 400 000 By this means it was found that after mixing 0 3% hydrochloric acid with an excess of bismuth carbonate the amount of bismuth in the filtrate was not more than 1 part in 160 000 To test the astringency of this concentration of bismuth, a sample of the filtrate was added to an aqueous solution of egg-albumin No coagulum was produced, indicating that the astringent effect of the dissolved bismuth was negligible The question arises as to whether bismuth carbonate is soluble in the organic acids of the gastric juice It has been shown that lactic acid is formed in the stomach only when free hydrochloric acid is absent or diminished—less than 20 c cm N/10% The solubility of bismuth carbonate in N/10 lactic acid was estimated It was found to be approximately 1 part in 300,000 Here again, no astringent action was perceptible when measured by the effect of the solution upon especially having regard to a decision in the House of Lords (1935) when workers breaking down shale, which though not silica rock in itself contained small lenticles of quartz, were considered to be in an occupation scheduled under that act

SUMMARY

Stourbridge clayminers are exposed to dust containing free silica

A case is described in which the autopsy reveals that the pathological condition is silico-anthracosis

Two other cases are described with similar occupational and medical histories and radiological appearances, these are therefore presumed to be suffering from the same pathological condition

These clayminers should be eligible for compensation under the provisions made for cases of silicosis

My thanks are due to Dr A Meiklejohn for standing godfather to this paper, to Dr W Stewart and Dr Leslie Bold for their cooperation, to Mr H E Monk F I C and Mr E R Nind, F I C, for their work on the chemical analysis, and the colliery authorities for their courtesy and help, finally, to Mr F Fitzhugh for his help in the preparation of this paper

A CASE OF SYPHILIS OF THE LUNGS

ARNOLD CLARK, M D LOND, M R C P
TUBERCULOSIS OFFICER FOR DORSET, CONSULTING PHYSICIAN,
PORTWEY (E M S) HOSPITAL, WEYMOUTH

THE scarcity of recorded cases of syphilis of the lungs may partly be due to the infrequency with which it is recognised and the belief that antemortem diagnosis cannot be established[1] The object of publishing this case is to show that a diagnosis can be arrived at during the patient's life and to help in establishing clinical data on which a diagnosis can be made

A widow, aged 54, was asked to attend a clinic under the tuberculosis scheme because she had been notified as suffering from "tuberculous disease of the malar bone" Her occupation was domestic duties Apart from an intractable ulcer on her left leg in 1927 she had always been healthy until 1936, when she began to suffer from cough, with small amounts of sputum streaked from time to time, lassitude and dyspnœa Dyspnœa had only become pronounced during the previous few months, when her duties had become too much for her Has one grown up son No history of miscarriage Her husband died in 1919 at the age of 37 from "growth on the brain" First sought medical advice for a swelling over the left temporo frontal region which developed in 1937 and for which she received treatment from her doctor for 8 months The swelling was excised at the local hospital in January, 1938, but a chronic discharge persisted until December, 1938 About this time she developed a similar swelling over the left malar bone which was incised at the same hospital in November, 1938

At her first attendance at the clinic on March 2, 1939, the lower of the two incisions was weeping slightly while the upper had healed completely Weight 8 st 5½ lb, best known weight 10 st The chest was symmetrical Some restricted movement of the left upper half where the percussion note and air entry were impaired but no adventitious sounds were detected Apex beat in normal position Heart-sounds normal B P 145/95 mm Hg Pulse rate 70 per min, regular Mentality and memory good Pupils equal and reacted to light and accommodation No objective sensory changes Complained of pain over left femur not unlike tabetic pains No rombergism Tendon reflexes normal Healed ulcer with tissue paper appearance over upper end of left fibula No tubercle bacilli found in sputum (no further examinations made because cough had gone by next attendance) Blood Wassermann and Kahn reactions + + Radiogram of chest on March 2 (fig I, plate) arch of aorta slightly prominent and contains a calcified plaque, left upper zone contains a large opaque area irregular in outline from which radiate processes connecting it with a similar but smaller opacity in lower zone lying near root

For various reasons only ambulatory treatment could be undertaken Antisyphilitic treatment was instituted immediately the true cause of the lesion was suspected She attended a local treatment centre—and still continues to do so, for her Wassermann and Kahn reactions are still positive She was asked to attend for X-ray examination fortnightly but failed to do so, and her second attendance was not until April 20, 1939, when the film (fig II) already showed considerable absorption of the opacities originally noted Her symptoms, too, were much improved, she could do a day's work and walk upstairs without undue dyspnœa, her cough had disappeared, the sinus over her left malar bone had healed Further radiograms showed progressive improvement At her last attendance on Jan 20, 1941, she was in "better health than ever" (fig III) Despite "winter colds" there is no persistent cough Weight 8 st 10¼ lb

This appears to be a case of the gummatous form of lung syphilis[2] The criteria on which the diagnosis is based are

(1) Length of history
(2) Positive serological findings
(3) Absence of tubercle bacilli in sputum
(4) Prompt relief of symptoms and progressive, rapid and maintained improvement in X ray appearances following antisyphilitic treatment
(5) Presence of syphilitic lesions elsewhere

I should like to thank Dr T W Stallybrass, the county M O H, for permission to publish this case, and Dr T I Cooper, the county pathologist, for the laboratory investigations

---

ACTION OF BISMUTH CARBONATE IN GASTRIC DISEASE

STANLEY ALSTEAD, M D LPOOL, M R C P
ROBERT POLLOK LECTURER IN PHARMACOLOGY AND THERAPEUTICS,
UNIVERSITY OF GLASGOW, ASSISTANT VISITING PHYSICIAN,
STOBHILL HOSPITAL, GLASGOW

THE gastric antacids and sedatives constitute an important group of therapeutic agents, and it is comparatively easy to confirm their effectiveness In certain kinds of gastroduodenal disease temporary relief of pain consistently follows the administration of an antacid in a high proportion of cases The action of these compounds on the pH of the gastric contents is also demonstrable by observations made in the course of fractional test-meals

Bismuth carbonate and bismuth subnitrate are included in this group of drugs The employment of these basic salts of bismuth dates from the use of the subnitrate by Odier in 1803 It is noteworthy, however, that he used this salt in doses of only one grain and always prescribed with it magnesia (gr 10) and sugar (gr 10)[*] Odier thought this compound powder an infallible remedy for gripe, and since then bismuth preparations have enjoyed a vogue in the treatment of gastroduodenal lesions MacKenna (1931), in a paper on the history of bismuth mentions that in 1852 Chambers in England, and Kussmaul in Germany, advocated bismuth salts in the treatment of gastric ulcer, Kussmaul recommended the subnitrate in doses of 10–20 grammes daily In recent years bismuth subnitrate has fallen into disrepute, after the publication of a number of cases of nitrite poisoning attributed to the reduction of the nitrate by intestinal bacteria Bismuth carbonate, on the other hand, is still widely used in the treatment of gastroduodenal disease especially in cases of peptic ulcer and gastritis According to standard works on pharmacology (Cushny 1941 Poulsson 1940 Dilling 1940) this insoluble salt acts mainly by coating the gastroduodenal mucosa, thus behaving as a protective in much the same way as a discovered and neither of them benefited from the magnesium hydroxide

[2] Shanks, S C Kerley, P and Twining, E W Text book of X Ray Diagnosis London, 1938 Vol I p 269

[*] In the third edition of Odier's Manual published in 1821 the author is less conservative and recommends the 'white oxide of bismuth' in doses of gr 6–12 four times daily He also states that he discovered the remedy in 1786

These results were examined statistically by Dr Richard A Robb of the mathematics department in the University of Glasgow, and his findings may be summarised as follows

The effects of the inert powders (lactose and dried milk) is shown by contingency tables where the 21 patients are classified according as they have or have not disease, and according as they do or do not get relief from the powders As is to be expected, the classifications are independent, using the χ^2 test, that is to say, these inert powders gave as much relief to patients with disease as to those with disease not proved The same analysis when applied to the results obtained from bismuth carbonate again shows that the classifications are independent—the response of the patients was the same as when the inert powders were used

It was found possible to distinguish between the degrees of relief obtained from the treatment, so that further analyses of the data were made Again the figures indicate that there was no difference in the response of the patients to the three powders—bismuth carbonate lactose and dried milk If the 5 patients with no evidence of disease are excluded from the series and the analysis confined to those known to be suffering from gastro-duodenal disease, the results are the same

DISCUSSION

The investigations provide no evidence in favour of the view that bismuth carbonate in therapeutic doses is a reliable means of protecting the gastric mucosa After administration by mouth, the salt collects in the most dependent part of the stomach and there is a tendency for it to adhere to the mucous membrane in a relatively small area in the prepyloric region, but the ulcer-bearing area of the stomach is rarely affected

Bismuth carbonate may exert an astringent action on the empty stomach but the investigations show that even under favourable conditions this must be very slight, and in practice it must be rendered negligible by the combination of the minute amount of bismuth in solution with the mucoprotein of the gastric juice It is clear that when a gastric astringent is required other drugs offer a much more reliable method of treatment—e g tannic acid in the form of glycerin of tannic acid (B P)

Previous workers have shown that the chemical properties of bismuth carbonate make it an unsatisfactory antacid for clinical purposes and this conclusion is confirmed The antacid effect following therapeutic doses of bismuth carbonate is seen to be trivial or entirely absent Although very large doses produce appreciable changes in gastric acidity, even these are transient and the side effects of such large quantities especially constipation, cannot be disregarded There seems therefore to be little justification for the view that bismuth carbonate is a valuable adjuvant to powerful antacids such as magnesia The negative results obtained in test-meals are in keeping with the conclusions drawn from the therapeutic trials in patients suffering from gastro-duodenal disease when it was found that bismuth carbonate was no more valuable than powdered milk or lactose in relieving pain The findings as a whole support the view expressed by Hurst (1929) "It seems very improbable that the small dose of bismuth [carbonate] given with sodium bicarbonate in the usual alkaline mixtures, powders and tablets can exert an action of any kind in the stomach Its use should therefore be discouraged as it has the disadvantage of making the stools black so that the immediate recognition of slight melæna by the patient becomes impossible"

SUMMARY

The action of bismuth carbonate as an antacid was investigated in vitro and also by fractional test-meals in healthy and ulcer subjects Therapeutic doses were found to have only a negligible effect on gastric acidity

Hydrochloric acid or lactic acid of the strengths found in the stomach dissolve only a trace of bismuth carbonate Such solutions were found to have no astringent action on egg albumin

In 12 patients who were screened after taking doses of bismuth carbonate the drug formed a pool at the most dependent part of the stomach and showed no tendency to distribute itself over the lining of the stomach or to fill the crater of an ulcer when one was present

Three powders consisting of bismuth carbonate lactose and dried milk respectively were given to 21 patients complaining of abdominal pain thought to be due to abnormalities of the stomach or duodenum and they were asked to say which powder relieved their pain No significant difference was found in the pain-relieving effects of the three powders Six of the patients with demonstrable disease of the stomach were then given magnesium hydroxide all of them reported much greater relief than from any of the powders

It is concluded that in therapeutic doses bismuth carbonate has a negligible effect as an antacid or as an astringent dressing for the gastric mucosa, and that it is of no value for the relief of pain in gastroduodenal disease

I desire to thank Prof Noah Morris for his interest in this work, Mr David T Gibson, D Sc, of the chemistry department in the university, and Dr W D. C McCrone, assistant radiologist at Stobhill Hospital, for advice and criticism, and Sister H D Collins and Sister J E Rennie for their coöperation

BLAST INJURY OF THE LUNGS

J N O'REILLY,
D M. OXFD, M R C P
MEDICAL SUPERINTENDENT OF ST MARGARET S EMERGENCY HOSPITAL

S ROODHOUSE GLOYNE,
M D LEEDS,
PATHOLOGIST TO THE HOSPITAL AND TO THE LONDON CHEST HOSPITAL

MUCH attention has been given lately to the effects of the blast of high explosive on people in the immediate neighbourhood Apart from its scientific interest a careful study of the subject is of great importance in deciding correct treatment, and we are therefore recording our experiences in the treatment of a series of cases of men suffering from blast injuries of varying severity

On Nov 18, 1940 a high-explosive bomb dropped close to a wooden hut housing a number of soldiers The hut was demolished and almost all of the men within were affected to some extent Of those admitted to hospital 9 were dead on arrival or died within a few minutes The majority of these 9 had no external injury and had not been buried, no autopsy could be held on them because of pressure of work in looking after the living A number of other men were picked up dead but were taken straight to a mortuary they were examined by a medical officer who also reported little evidence of external injury Of the men who survived for an appreciable time after admission 8 were suffering from severe pulmonary blast, 2 others had severe blast injuries associated with injury to the chest wall, and 7 had lesser degrees of blast injury from which they made uninterrupted recoveries These 17 cases form the subject of this paper

The men were admitted within two hours of exposure to H E blast The circumstances have been reconstructed with some care and there is little doubt that with two exceptions, cases 9 and 10, these men suffered from the effects of blast only The men were billeted in wooden huts which formed part of a small pleasure fair ground There was a bright moon with a thin layer of cloud A sentry observed the descent of a parachute and ran to warn his sleeping comrades He did not succeed in rousing them before the bomb struck a wooden tower close to the huts The explosion was of such violence as seriously to shake the hospital over two miles away The huts were completely demolished Rescue work was begun immediately and many of the men were got out at once Others were buried under debris which was not of a heavy character None of the patients egg-albumin As a control, the same solution of egg-albumin was used to demonstrate the astringency of dilute solutions of tannic acid (B P) Coagulation of the protein was readily produced by a 0 05% solution of tannic acid

The solubility of bismuth carbonate in gastric juice was investigated Samples of juice were obtained from 4 patients, the total acidity ranged from 10 c cm to 56 c cm N/10% and the free hydrochloric acid from zero to 48 c cm N/10% The samples were mixed with an excess of bismuth carbonate and kept at body-temperature for two hours Some of the juice was then decanted and tested for dissolved bismuth The stannous-chloride test gave a negative result in all cases

The conclusion that only a minute trace of bismuth dissolves in weak hydrochloric acid is not incompatible with the observation that bismuth carbonate can increase the pH of the solution In the presence of hydrochloric acid bismuth carbonate forms bismuth oxychloride, and thus, within certain limits, it diminishes the hydrogen-ion concentration The following test was done to demonstrate this action

An excess of bismuth carbonate was added to about 50 c cm of hydrochloric acid which had a pH of 0 7 The mixture was shaken and set aside for a few minutes It was then filtered and the filtrate was found to have a pH of 1 1 The residue was washed with distilled water until free of hydrochloric acid—that is, until the washings failed to give a precipitate with silver nitrate—and it was then dissolved in nitric acid (B P) About 5 c cm of the nitric acid filtrate was tested for chloride by means of silver nitrate A heavy white precipitate formed, proving that abundant chloride was now present in solution As a " blank " bismuth carbonate was dissolved in strong nitric acid, this solution gave no precipitate with silver nitrate

Radiological findings—Seventeen observations were made on 12 patients, 2 of whom had large penetrating ulcers (about 1 5 cm in diameter) situated on the lesser curvature approximately 7 cm from the pylorus (fig III, plate) On screening while the patient was standing, the aqueous suspension of bismuth carbonate was seen to trickle in a narrow stream to the most dependent part of the stomach where it formed a shallow pool (fig IV) A small proportion remained in the track between the cardia and the lowest part of the greater curvature There appeared to be no tendency for the drug to distribute itself over the whole lining of the stomach, and no evidence was obtained for Cushny's (1941) statement that bismuth carbonate " is later distributed evenly over the surface and forms a continuous sheet over any ulceration " Even after appropriate manual palpation and alteration of the patient's posture the distribution of the bismuth carbonate was not permanently altered, with the resumption of the erect posture the pool immediately reappeared in the original position Repeated efforts to fill the large ulcer craters failed even after giving gr 90 of the drug

Nine of the patients were investigated to discover the effect of taking a meal about half an hour after a dose of bismuth carbonate They received 2 g (gr 30) of the salt about half an hour before breakfast and a radiological examination was made 2 hours later In 5 of this series there was no sign of the drug, apparently it had mixed with the foodstuff and was carried through the pylorus during the early stages of emptying of the stomach In the remaining 4 patients a variable amount of the drug had been retained at 2 hours, it was invariably confined to the prepyloric region of the greater curvature as in fig VI Complete disappearance of the salt was accelerated by the taking of more food In one patient, however, it persisted for at least 28 hours although five meals had been taken during this time (fig VII) When there was food in the stomach at the time of administration of the drug, the suspension of bismuth carbonate was seen to follow the usual course, but the stream was soon broken up into several smaller ones by the food masses, and the bulk of the salt accumulated about the middle of the body of the stomach Thereafter the drug gradually dispersed and became intimately mixed with the gastric contents (fig V)

Therapeutic tests—Observations were made on 21 male patients admitted to a medical ward of Stobhill Hospital on account of abdominal pain thought to be associated with abnormalities of the stomach or duodenum After the usual clinical examination the patients were investigated radiographically, a fractional test-meal was done, and the stools were tested for occult blood The patients were given the ordinary ward diet Each patient was then presented with a batch of 18 powders, 6 of these contained bismuth carbonate gr 30, coloured pink with a trace of azorubrum (B P C) 6 were composed of lactose, the quantity (gr 40) having a similar bulk to the bismuth carbonate powders, and these were tinted with methylene-blue, 6 were made of dried milk, which had a natural light yellow colour

The choice of substances that can be used as controls is very limited Many compounds which are inert when applied externally act as adsorbent antacids in the stomach Lactose appears to be the only substance, easily obtainable, which is entirely satisfactory Milk is an antacid, neutralising its own volume of gastric juice (Freezer et al 1928), and powdered milk must be regarded as an antacid when adequate quantities are used In doses of about gr 30, however, this effect is hardly likely to be appreciable This view is supported by the results of the present investigation, and milk powder in small doses was regarded as an inert substance and was accordingly used as an additional control

The patient was directed to take the powders in any order and to decide in the course of a week or ten days which of them, if any, gave relief from pain It was emphasised that he must not take a powder unless he had pain, and in the event of a powder failing to give relief he was to wait for half an hour before trying one of the others Effects other than the action on pain were ignored The composition of the powders was not disclosed to the patients, or to the nursing staff with the exception of the ward-sister, the powders were referred to only by colour The group of patients was not selected except in so far as it was found necessary to abandon the investigation in a few patients who were not sufficiently intelligent to cooperate satisfactorily No precautions were taken to prevent conversation between patients who were receiving treatment with the powders at the same time The patients' descriptions of the effects of the powders were roughly classified as (*a*) no relief, (*b*) doubtful, (*c*) definite relief, (*d*) pronounced relief The last two were considered to be significant In 16 patients there was objective evidence of disease duodenal ulcer or scarring 10, gastric ulcer 2, gastritis 1, gastric spasm 1, simple hyperchlorhydria 2 In 5 patients no signs of disease were discovered The answers are summarised in the following table, several of the patients reported relief from more than one powder, and therefore the number of answers exceeds the number of patients

EFFECT ON GASTRODUODENAL PAIN OF BISMUTH CARBONATE AND CONTROL POWDERS

—	Whole series	Disease proved	Disease not proved
Relief from—			
Pink powder (bism carb)	6	6	0
Blue powder (lactose)	8	6	2
Yellow powder (dried milk)	6	5	1
Unrelieved by any of powders	5	3	2

Among the 6 patients who appeared to get relief from the bismuth carbonate, 4 were also relieved by taking lactose or dried milk, and 2 experienced no relief from either of these pharmacologically inert powders None of the patients said that the three powders gave equal relief

Eight of the patients, after completing the course of treatment with the coloured powders, were given a similar opportunity to express an opinion on the effectiveness of a " white powder " which was magnesium oxide given in doses of gr 6 (Mist magnes hydrox ℳ 120) The object of using this substance was to determine whether the pains were amenable to treatment by a drug which is known to have a powerful antacid action Six of these reported immediate relief from pain, and the benefit far exceeded any that had been obtained from the coloured powders It is noteworthy that lesions of the stomach or duodenum had been demonstrated in all of these 6 patients in the other 2 patients no disease had been

The cause of the recurrent hæmorrhages and their relation to the accentuated pulmonary second sound are obscure

Case 5 —Severe shock, complained of pain in chest Dyspnœa but no gross cyanosis Highly resonant percussion note and much diminished air-entry at left base Elsewhere percussion note normal Scattered râles over rest of both lung fields Pneumothorax on left side diagnosed and confirmed radiologically (fig IV) Next day breath sounds at left base tubular paravertebrally and absent in axillary line Few crepitations still audible elsewhere, notably at right base

Very gradual improvement in physical signs until on Jan 7, 1941, chest appeared normal General condition improved rapidly after first few days and patient made no complaints

Case 6 —Moderately severe shock, considerable dyspnœa and cyanosis Complained of pain in chest and within an hour had brisk hæmoptysis of 5 oz which relieved his pain Rhonchi all over chest and was wheezing like an asthmatic It was thought that condition might be due to inhaled dust, but no evidence of this either then or later Resuscitation by oxygen and warmth, T 99 6° F Next morning much better, still cyanosed but breathing more easily Radiogram (fig V) showed characteristic mottling in both lungs Still rather wheezy By evening, 36 hours after the incident, temperature 101° F, clinical signs of consolidation at left base Nov 20 signs of consolidation at left base more definite and some râles audible, right base also congested, rhonchi over rest of lung fields had diminished, T 104° F, dyspnœic, cyanosed and delirious Nov 21 general condition much improved, left base still consolidated and crepitations audible at right base, T 101° F Nov 22 very much improved, left base clearing, basal crepitations on both sides, still a little wheezy

Thereafter the patient made a good recovery though air-entry remained weak at the bases for several weeks The final radiogram showed complete resolution

Case 7 —Severe shock, pallor, cyanosis and dyspnœa Complained of pain in chest and abdomen Resuscitation measures warmth and oxygen and plasma transfusion Air-entry poor and râles present all over both lungs Most striking clinical feature was completely rigid and painful abdomen Laparotomy decided on, nothing found except few small subserous hæmorrhages, abdomen closed Nov 19 air-entry into right base diminished and percussion note impaired, spitting up small quantities of dark blood, T 104° F, P 142, later in day tubular breathing became audible at right base Nov 20 very ill, right base dull to percussion and tubular breathing still a feature, T 105° F, complained of diplopia and had a convulsive movement of frontalis muscle, apparently a tic Nov 21 dull in right axilla and base, breath sounds weak with some râles few rhonchi at the left base, where breath sounds also weak. Nov 22 signs as before, radiogram (fig VI) shows collapse of right lower lobe, T 102° F. Nov 28 general improvement, breath-sounds still weak in right axilla and at base, tic still present, diplopia remains, but only on lateral deviation of more than 45°, no obvious weakness of oculomotor muscles Nov 29 T 103° F, abdominal wound slightly septic, tubular breathing at right base with some rales, breath sounds weak in axilla, normal over middle lobe, mucopurulent sputum Thereafter patient made gradual recovery with re expansion of the collapsed lobe

The diplopia is difficult to explain It may have been due to a cerebral contusion Eventually it disappeared completely

Case 8 —Some shock, bruising and pain in chest, particularly on right Breath-sounds weak at both bases, no added sounds Nov 21 some cough and pain, mucopurulent sputum, no blood, no dyspnœa Nov 23 still coughing, mucopurulent sputum, no added sounds Some pain X ray showed no abnormality Nov 27 pain in region of right base and axilla, breath sounds weak, percussion note normal, no added sounds, pain in side on deep breathing T up to 100° F and has not settled since Nov 24 general malaise, pain on breathing, no definite signs except weak breath sounds at right base Nov 29 no change, T 102° F Nov 30 T 101° F pain in chest still, impaired note at right base with weak tubular breathing and few râles, sputum purulent Dec 1 much improved, less pain, breath-sounds very weak, no added sounds Thereafter there was gradual resolution, still incomplete 6 weeks later

CASES WITH DAMAGE TO CHEST WALL

Both cases 9 and 10 had injuries to the chest wall Their clinical appearance, however, was that of blast injury to the lungs Case 9 had all the characteristics of severe pulmonary injury and damage to the chest wall was discovered only at autopsy.

Case 9 —Severe shock, dyspnœa and cyanosis Pain retrosternally and on both sides of chest, particularly on deep breathing Complained continually of severe pain in abdomen Normal percussion note with poor air-entry all over chest particularly at bases Coarse râles all over both lungs Abdomen rigid and tender, no shifting dullness After resuscitation improved slightly but remained dyspnœic and cyanosed Pulse rapid and of poor volume Patient died 14 hours after explosion

Autopsy —Well covered No external evidence of injury Simple transverse fracture of sternum and fracture of pelvis Massive hæmorrhages in posterior mediastinum in loose tissue behind and around great vessels, apparently due to rupture of small veins, for no damage to large vessels could be detected Hæmorrhages also found in extrapleural tissues of intercostal spaces, so that inside of thorax appeared black between white bands of ribs No evidence of visceral injury in abdomen Gross hæmorrhages in psoas sheaths on both sides Visceral pleuræ showed large irregular blotches of dark red hæmorrhage and areas of ecchymoses Lungs much congested with here and there large irregular hæmorrhages similar to those in pleura Standing out clearly by contrast on congested background were many pin point yellowish white areas of early bronchopneumonia Right apex and anterior free border of lung emphysematous, at base of lower lobe on this side was small collection of dilated bronchi suggesting developmental bronchiectasis, unrelated to injury Sections of bronchial wall showed intense infiltration of mucosa and submucosal layers with blood corpuscles and blood pigment Histological appearances resembled those of case 1, but rupture of elastic fibres less definite Numerous areas of very early bronchopneumonia, containing short chains of streptococci

Case 10 —Moderate shock Complained of pain in chest especially on right Breath-sounds weak all over but especially at right base Crepitus audible and palpable, diagnosis of fractured ribs made Radiologically 8th and 9th right ribs seen to be fractured, small hæmothorax Areas of mottling in both zones Pain and poor air entry continued for some days but patient made uninterrupted recovery X-ray appearances cleared up in a few days

SLIGHT CASES

The remaining cases are not recorded in detail, since on account of pressure of work no other investigations were carried out They are none the less to be considered as mild cases of blast injury

Cases 11–17 —These 7 men were obviously less ill than any of foregoing Came in somewhat shocked and dyspnœic with some cyanosis and pain in chest and back Breath sounds distant, no added sounds Percussion note normal Symptoms disappeared in a few days and recovery was smooth

CLINICAL FEATURES

The features of the cases which impressed the clinical observer were as follows

Shock was profound in the 5 more serious cases Blood-pressures were not taken, but pallor, cyanosis and rapidity and poor volume of the pulse were noted The other 5 patients described in detail were severely shocked, though less so than the foregoing. The remaining cases were definitely though not dangerously shocked

Dyspnœa was a constant feature of all the patients The difficulty of respiration was due in part to pain and in part to extreme bulging of the chest, which appeared to be in the position of almost full inspiration This bulging has also been noted by Dean, Thomas and Allison (1940) Dyspnœa continued till death in fatal cases, it remitted to some extent after 24 hours in cases 5, 6 and 7, and became noticeable again as the signs of pneumonia developed, in cases 4 and 8 it disappeared within 24 hours

Cyanosis was obvious in the most severe cases and present in all the others In cases 1, 2, 3 and 9 it remained till death In cases 5 6 and 7 it disappeared within 24 hours Thereafter the picture was confused by the administration of sulphapyridine The other cases had cyanosis on admission but lost it after 24 hours.

included in this paper were buried so far as could be ascertained Other patients, who were known to have been pinned under beams have not been included , some of these had injuries requiring surgical treatment, but one of the striking things about this incident was the absence of severe crushed or lacerated wounds The men were in bed on the ground floor, and the complicating factors of trauma due either to falling debris or to being blown against walls were absent except in cases 9 and 10 The circumstances of the injury comply with the criteria set up by Zuckerman (1940) in his experimental work as nearly as is likely to be found in human cases

SEVERE CASES

CASE 1 —Severely shocked and dyspnœic , complained of great pain in chest and abdomen Very restless in spite of morphia gr ½ Great diminution of air-entry with numerous coarse râles over whole chest , percussion unimpaired except at right base Abdomen rigid and painful, and these signs dominated the picture After resuscitation with warmth, oxygen and a plasma transfusion (1 pint) was taken to theatre and laparotomy performed Few small subserous hæmorrhages found but no gross trauma Patient collapsed and died on table about 4 hours after original injury

Autopsy —Well covered No sign of injury except superficial abrasion about 4 in by 2½ in over right shin Clean laparotomy wound *Neck* Carotid sheath and great vessels surrounded with partially clotted blood No tear discovered in vessels Thymus persistent, but appeared healthy and contained no hæmorrhages *Thorax* Each pleural sac contained about 2 pints fluid blood, but no ruptured vessels found No adhesions Hæmorrhage had occurred outside parietal pleura, most obvious along line of ribs Irregularly shaped bright red hæmorrhages also seen beneath visceral pleura , most extensive posteriorly Mediastinum filled with blood mostly fluid *Trachea and main bronchi* exhibited intense congestion of mucous membrane with numerous small hæmorrhages *Lungs* on section were bright red, resembling congestive stage of extensive early lobar pneumonia Congestion best seen in peripheral portions, where elongated bands of dark red hæmorrhage were running parallel with pleura and about ½ in beneath it Numerous small rounded hæmorrhages in other parts of lungs On the whole, these appearances more definite in lower than upper lobes, and more in posterior than anterior portions Nothing to suggest disease prior to injury *Pericardium* showed no free blood, but small hæmorrhages beneath visceral layer *Heart* healthy but contained fluid blood in all chambers *Abdomen* Peritoneum contained no free blood Some small hæmorrhages beneath serous coat over cæcum and appendix and beneath peritoneum over psoas muscle on right side Few subperitoneal hæmorrhages in left hypochondrium, and beneath serous coat of small intestine, but bowel contained no blood and showed no ulceration Small subcapsular hæmorrhages in spleen, kidneys and liver, but these organs otherwise healthy No lesions in suprarenals Gall bladder healthy , no hæmorrhages Head of pancreas contained hæmorrhages Bladder healthy and contained clear urine No fractures noted *Central nervous system* Brain congested with some small submeningeal hæmorrhages over vertex and base A little free blood in ventricles No lesions in substance of brain

Histology —Lesions in lungs patchy In places structure was little, if at all, altered , in others intense outpouring of erythrocytes completely obscured structure Between these two extremes were areas, whose air spaces were still clearly outlined with intact capillary loops, and were filled with erythrocytes Fibrin and free blood pigment also present in small amounts, and scattered throughout the air spaces were numerous polymorphonuclear leucocytes and macrophages Latter contained considerable amount of blood-pigment, and were morphologically identical with heart-failure cell seen in passive congestion Most of capillaries bounding air spaces contained only a few red cells , some loops contained none at all Elastic fibres ruptured in several places Some areas showed nothing but masses of erythrocytes with isolated fragments of ruptured elastic tissue masking alveolar structure Many respiratory bronchioles in these areas also filled with erythrocytes and fibrin, while small bronchi mostly showed desquamation of epithelium with collections of leucocytes filling lumen In sections of peripheral portions of lung, deep layer of pleura contained masses of erythrocytes lying between collagenous fibres , in places, this outpouring of red cells had separated pleura from lung beneath Few streptococci seen, but no areas of bronchopneumonia

CASE 2 —Grossly shocked, dyspnœic and cyanotic, complaining of pain in chest retrosternally and in both flank Rather restless Given usual resuscitation treatment of warmth, morphia and oxygen , on account of condition not moved from resuscitation ward for sixteen hours, when temperature was 100° F and he had recovered sufficiently to justify moving Diminished air entry and coarse râles all over chest, without alteration of percussion note Radiogram (fig I, plate) showed heavy mottling in whole left lung field and a right mid-zone Abdomen rigid and tender During next 12 hours was kept warm and recovered to some extent Vomited several times coffee ground vomitus, not examined for blood Next day considered well enough for transfer to Chest Unit under care of Prof R V Christie, to whom we are indebted for subsequent history On arrival was restless and ill with high colour and some cyanosis , dyspnœic , drank greedily but still vomiting large amounts of thin brownish fluid which gave faintly positive guaiacum reaction Diminished movement on left side of chest and many râles and rhonchi audible, especially in left axilla During next few hours improved, though still irritable, dyspnœic and rather more " bubbly " Venesection attempted twice, second time successfully, with a great relief of restlessness and dyspnœa Vomiting also ceased Few hours later (48 hr after incident), became restless and delirious No râles then audible Soon afterwards collapsed and died in spite of attempted blood transfusion

Autopsy (Professor Hadfield) —No gross injury Some hæmorrhages between parietal pleura and thoracic wall At least two thirds of left lung and half of right lung consolidated Extensive dark subpleural hæmorrhages, continuous with deeply seated hæmorrhages Consolidated parts colour of dark venous blood clot, but " their ill defined edges were bright red, fading off gradually into normally coloured lung Throughout this dark coloured consolidated lung there were many scattered areas, ashen grey in colour and sharply demarcated from the surrounding tissues "

Histology —Appearances bore striking resemblance to those found in hæmorrhagic infarct Little evidence of widespread alveolar rupture and Hadfield took the view that bleeding was due to diapedesis In the grey areas each alveolus "contained a precisely staining close marked film network in the meshes of which considerable numbers of wandering cells and partially hæmolysed red cells were lying The general appearance bore a rather striking superficial resemblance to that of lobar pneumonia in the stage of red hepatisation" Wandering cells predominantly monocytic

CASE 3 —Severe shock, pallor, dyspnœa and cyanosis, with great pain in chest and back Distant breath sounds, with coarse râles all over both lung fields Morphia and oxygen given and some degree of recovery (T 104° F) Next day appeared somewhat better, but still very ill (T 102° F) On 20th, 48 hours after injury, was again much worse Impaired percussion note and tubular breathing at right base—i e , clinically a lobar pneumonia Scattered râles still audible over rest of both lungs Radiogram (fig II) showed heavy mottling over both lung fields with consolidation at right base Became worse and died about 55 hours after incident

Autopsy —Massive hæmorrhages into substance of lung tissue on both sides, with evidence of consolidation at right base Mediastinal and extrapleural hæmorrhages present Unfortunately no portions of lungs preserved for section No evidence of other injury

CASE 4 —Shocked, though less so than previous cases, some dyspnœa and cyanosis Diminished air entry at both bases and scattered râles over both lung fields, Percussion note normal Complained of some pains in chest and abdomen, but these grew less severe after a time (T 101.2° F) Next day much better Still diminished air entry at lung bases and scattered crepitations over whole of both lungs Radiogram (fig III) showed heavy mottling in left lung, less in right Transferred to care of Professor Christie who has provided subsequent history On arrival no dyspnœa or cyanosis Nothing abnormal heard on auscultation anteriorly Nov 21 bruising of right chest wall , diminished movement on left , pulmonary second sounds (P 2) accentuated , B P 140/88 mm Hg Nov 23 vital capacity 2500 c cm Dec 2 vital capacity 3800 c cm ; X ray clear , P 2 less accentuated Dec 9 P 2 more accentuated , ½ oz bright blood coughed up , X ray normal , no abnormal physical signs Dec 15 coughed up dark red blood , P 2 still very loud Jan 5, 1941 bright red blood intimately mixed with mucus coughed up , P 2 + +

and radiologically demonstrable pneumothorax Case 6 developed pneumonia at the left base 36 hours after the blast He had a temperature of 101° rising to 104° F and had some hours of delirium Case 7 had clinical signs of pneumonia 24 hours after the blast This was confirmed radiologically, though it was shown shortly afterwards that he had collapse of the right lower lobe Case 8 was peculiar in that his lungs were clear for 8 days after the explosion, though he had some pain, cough with sputum and an irregular temperature He then complained of sharp pain in his right side, worse on inspiration, and after a further 36 hours had typical clinical and radiological pneumonia of the right lower lobe All the cases were treated with sulphapyridine and the duration of the pneumonia was short, with the exception of case 7 who was seriously ill for some days Pathological examination of case 9 showed, however, that the inflammatory condition was a bronchopneumonia The correct explanation seems to be that the physical signs are largely due to the effusion of blood which corresponds roughly to the stage of red hepatisation of lobar pneumonia and may be expected to give rise to the same physical signs

The less severely blasted cases 11–17 showed no definite physical signs except the bulging of the chest wall with its associated limitation of movement and respiratory excursion The condition became normal in 7–10 days

Radiograms of the chest were taken within 72 hours in cases 2, 3, 4, 5, 6, 7 and 10 Cases 1 and 9 were too ill to disturb The severe cases 2, 3 and 4 all show similar pictures (figs I, II and III) There is heavy mottling over large areas of the lung fields In case 2 it extends through the whole of the left lung field The right middle lobe is seriously affected and to a lesser extent the upper and lower lobes The picture reproduced in fig I was taken within 12 hours of injury

The radiogram of case 3, taken about 48 hours after the injury (fig II) shows the mottling scattered through both lung fields The dense shadow seen at the right base corresponds with an area of pseudo-pneumonic consolidation which was evident clinically and was found at autopsy

Case 4 was X rayed about 30 hours after injury Fig III shows the mottling scattered throughout the left lung and less densely through the right lung Next day the condition had cleared considerably except at the left base, where the shadowing was denser and more homogeneous Five days later the lung had largely cleared and subsequent radiograms showed no abnormality This heavy mottling must be taken as the characteristic radiological appearance after severe blast injury It is due to the interstitial and alveolar hæmorrhage and varies in density and extent with the clinical and pathological findings In severe non-fatal cases it clears rapidly pari-passu with the clinical signs, translucency of the lung being normal within 7 days A rather less severe case (case 6) shows similar mottling of both lung fields 24 hours after injury (fig V) These were still present four days after injury when the radiological appearances of a right basal pneumonia confirmed the physical signs, 10 days after the injury the mottling had disappeared though the lung striation was rather heavy

Case 5 showed a small spontaneous pneumothorax at the left base together with some mottling in the left mid-zone (fig IV) Both cleared up in the course of a few days

A radiogram of case 7 taken about 54 hours after blasting showed heavy mottling in the left mid-zone and collapse and consolidation of the right lower lobe (fig VI) After treatment the mottling cleared up in the course of 10 days while the collapsed lobe gradually re-expanded completely

Case 8 had no radiological lesions when first X rayed a week after the explosion, 4 days later he had some consolidation at the right base which resolved very slowly Case 10 showed similar mottling in the early stages, but cleared rapidly

PATHOLOGICAL FINDINGS

The most striking feature in the autopsies was the effusion of blood This varied from capillary oozing to large hæmorrhages in one case filling both pleural sacs and the tissues of the neck around the carotid sheath For the most part this blood remained fluid

Histologically the chief characteristics were (*a*) an extensive outpouring of erythrocytes, in places accompanied by fibrin formation and the accumulation of blood pigment, though these were not constant, (*b*) rupture of elastic tissue and capillaries in the most affected parts, and (*c*) secondary infection with streptococci and bronchopneumonia The function of the lungs must obviously have been impaired by the filling of respiratory bronchioles and air-spaces of large areas with blood, and by the rupture of the elastic tissue and capillaries If the initial period of shock could have been overcome, the blood corpuscles would presumably have been removed from the air-spaces by the tissue defences as they are in pneumonia, but ruptured elastic fibres and capillaries would not be likely to undergo repair Blast lung, therefore, may suffer both a temporary and permanent impairment of function, varying with the extent of the initial hæmorrhages

The presence of streptococci and bronchopneumonia is noteworthy Probably very few lungs are completely free from organisms even in health, and the risk of secondary infection in blast lung is not negligible

These investigations were made before Robb-Smith's paper (1941) on fat-embolism was published Subsequent investigation of the material with frozen sections did not show any emboli No pictures of the post-mortem specimens or slides can be reproduced owing to the destruction by enemy action of all the pathological material with the exception of one rather unsatisfactory specimen

TREATMENT

Shock —All cases of shock were treated by standard resuscitation methods—heat and morphia Heat was applied to the most serious cases by means of electric cradles, to others by hot bottles Morphia was given to control restlessness The initial dosage was gr $\frac{1}{3}$ This kept the majority of cases fairly quiet Cases 1 and 2 however were violently restless and complained of very great pain, and further doses of morphia gr $\frac{1}{6}$ had to be given It has been argued that morphia in shock has its dangers, particularly when there is damage to the lungs It seems likely, however, that the restlessness and distress of the patient are far more dangerous, and morphia is the only drug which will control them

Oxygen —Cases 2, 3, 4, 5, 6, 7 and 9 were given continuous oxygen Nasal catheters and spectacles were used as B L B mask were not supplied until later Some difficulties were experienced on account of the restlessness of the patients, but the relief afforded by oxygen was obvious Later, when B L B masks were available, they were used, particularly in the treatment of the pneumonias

Transfusions were given to cases 1, 2, 3, 7 and 9 The transfusion fluid was plasma for cases 1, 2 and 3, and blood for case 9, while case 7 received both plasma and blood None of the patients received more than 2 pints and the immediate transfusion of large quantities of plasma as recommended by Whitby and his co-workers (1941) was not undertaken It seems doubtful whether blood should be given unless there is concomitant hæmorrhage Christie observed that there was dilatation of the veins of the neck in one of the cases transferred to him (case 2) This man was much relieved both of his restlessness and the congestion of his lungs by venesection Christie further noted that prior to venesection, the hæmoglobin was 125% The indication is for plasma and not blood These conclusions are confirmed by the pathological findings It is difficult to see how a lung containing large areas of effused blood, often with rupture of the elastic tissue and capillaries, can benefit by blood-transfusion

Sulphapyridine was given prophylactically to cases 3, 5, 6 and 7 The dose was two tablets 4-hourly Case 8 received three tablets followed by one tablet 4-hourly This dosage appeared to have no effect in preventing the development of pneumonia When the pneumonia developed the dosage was increased to two tablets 3-hourly The temperature dropped to normal within 48 hours in cases 5 and 6 Case 7 had pyrexia lasting 6 days and settled down gradually Case 8 was treated for 48 hours, and then as the temperature had more or less settled, the sulphapyridine was stopped, it was started again when he developed signs of pneumonia 9 days later

Pain in the chest —Great pain was complained of by cases 2, 3 and 9, all of whom died The pain was of two distinguishable types—a central deep constant pain which was especially severe in cases 2 and 9 and a less severe pain felt more laterally and made worse by deep breathing The other patients complained of pain of both types, but it was noticeable that the less severely injured made little complaint of the central pain while complaining that the lateral pain was preventing them from breathing The central pain disappeared in the recovering cases after a few days, while the other pain remained for at least a week The cause of the pain in the chest is not clear The deep central pain may be related to the mediastinal hæmorrhages The innervation of the loose tissues of the mediastinum does not seem to have been well worked out, nor is it clear what is the effective pain stimulus The pain felt in the sides may have been due to contusion of the intercostal muscles, since at autopsy hæmorrhages into the spaces extrapleurally was a constant finding These hæmorrhages may also account for the bulging of the chest wall Contusion of the muscle might well result in spasm and contraction of the intercostal muscles causing the chest to assume the inspiratory position

Pain in the abdomen was an important feature of this series This was particularly striking in cases 1, 2, 3, 7 and 9 Cases 1 and 7 presented the appearance of acute abdominal disaster, having great pain and tenderness and rigid abdominal walls It was decided that laparotomy was necessary but nothing abnormal was found except a few small subserous hæmorrhages The abdomens were closed at once Case 1 died on the operating table It was then decided that the other cases who were not less like acute abdomens should be left Case 2 vomited at intervals during the first 24 hours, at times bringing up a brown vomit He was transferred to the care of Professor Christie, who noted the condition but decided to await events Cases 3 and 9 retained their abdominal tenderness and rigidity till death, but the signs ceased to dominate the clinical picture as they had done in the early stages Autopsies were carried out on cases 1 2, 3 and 9 In each of these hæmorrhages were found extrapleurally when the viscera were removed from the thorax, the intercostal spaces appearing black in contrast to the white bands of the ribs It seems possible that these hæmorrhages caused irritation of the intercostal nerves with consequent rigidity of the abdominal wall Zuckerman (1940) reports that this finding is also present in some experimental animals and finds the hæmorrhages continuous with those in the sheaths of the intercostal nerves He agrees that this may be the cause of the abdominal signs Another possible cause of the rigidity is that the abdominal muscles have themselves been damaged No investigation of this point was made Stress is laid on the clinical findings pointing to acute abdominal injury because of the logical course of treatment which they suggest The two laparotomies were undertaken in men whose lungs were known to be damaged and the negative findings were an unpleasant surprise At autopsy in case 1 lesions were found which made it unlikely that he would have lived Case 7 survived after a stormy period

Hæmoptysis —Free hæmoptysis was observed in cases 4 and 6 The amounts of blood were about 4–5 oz Both men were seriously affected by the blast, but neither at any time gave cause for grave anxiety Both men were undisturbed mentally by the hæmoptysis and both seemed somewhat easier after it The blood was noticed about an hour after the blasting and the duration of the free hæmoptysis was about 15 min Thereafter only small amounts of stained sputum were brought up Case 1 was noticed to have brightly stained froth in his air-passages while under the anæsthetic for his laparotomy Case 7 brought up a little dark-stained sputum during the day after the incident A few of the other men brought up dark blood in the sputum after 24–48 hours, but no other cases had free hæmoptysis Some of the men brought in dead or dying had blood staining in the nose and mouth without visible injury This accords with the more detailed observations made by Hadfield in his autopsies Other men who were operated on for lacerations and other injuries and are not included here were found to have blood-stained secretion in the trachea These patients were certainly suffering from blast Apart, however, from the 2 cases mentioned hæmoptysis was not a prominent symptom

Cough and sputum —None of the men were noticed to be coughing during the first twenty-four hours after blasting After this a number had coughs, some of which were troublesome The sputum was moderately thick, muco-purulent, and in several cases stained with dark blood for 24–48 hours In uncomplicated cases the cough and sputum disappeared in ten days, they persisted in the cases with severe late effects or complications

Restlessness was extreme in some cases Case 1 was quite uncontrollable even after repeated doses of morphia At autopsy some subarachnoid hæmorrhage was present in the vertical region There was no evidence of cranial injury Case 2 was restless during the first few hours but gradually became quieter After transfer to the Chest Unit he was again restless and continued so most of the time until his death Case 3 was exceedingly restless and controlled only by repeated doses of morphia Case 9, although in severe pain, was less restless than the foregoing He too had some subarachnoid hæmorrhage without obvious cranial injury The other cases were restless in proportion to the degree of injury but they were *all controlled by morphia*

Restlessness is therefore a constant symptom of blast injury and bears a direct relation to the severity of the damage The pathological findings suggest that it is not due to the pain but rather to an irritative lesion within the cranium This is supported by the observation that other victims of this incident whose principal injuries were caused by violence (e g , falling debris) were restless out of all proportion to the severity of their injuries The most extreme case was that of a man with a fractured femur who was almost maniacal for a week after the injury There was no gross evidence of cranial injury or pulmonary damage and the femur was successfully reduced a few hours after injury Certain other men with cranial and facial injuries gave no special trouble and one lad with extensive and painful burns was kept quiet without difficulty It seems justifiable to conclude that extreme restlessness is a result of blast injury to the head

Ruptured ear-drums were found in 25 men Some of these developed purulent otorrhœa which in a few cases proved very resistant to treatment

PHYSICAL AND RADIOLOGICAL SIGNS

The physical signs in the chest varied with the severity of the condition, but some were common to all patients in this series The chest was held about three-quarters expanded Respiratory movement was, therefore, much reduced, but was generally equal on the two sides Attempts at deep inspiration were limited by the expansion of the chest and the fact that the movement was painful Palpation gave no additional information The percussion note was resonant at all areas in the early stages On auscultation, the breath-sounds were notably weak especially at the bases Coarse rales were audible over the whole of the lung fields, numerous in the fatal cases 1, 2, 3 and 9 and less numerous in the other severe cases 4, 5 and 7 Case 6 was peculiar in that the added sounds were rhonchi The man was wheezing like an elderly bronchitic, though he had had no bronchitis previously The less severe cases, 8 and 10–17 inclusive, had no added sounds The rales persisted until death in cases 2, 3 and 9, where observations were made, though they became less numerous in the period of partial recovery which each patient showed Case 1 died without further observation on this point In cases 4, 5 and 7 the generalised rales became less numerous and disappeared in the course of a few days They appeared to persist longest at the lung bases

A striking feature was the development of the clinical appearance of lobar pneumonia at one lung base This was heralded by a more or less sharp rise of temperature Case 3 had a temperature of 104° F 12 hours after the blast After 48 hours the percussion note at the left base was much impaired with tubular breathing , this clinical finding was confirmed by X ray , he died a few hours later Case 5 showed a similar condition at the left base paravertebrally 30 hours after the blast, though here the picture was complicated by a small clinically

THE LANCET

LONDON SATURDAY, OCTOBER 11, 1941

BIPP AND ITS FRIENDS

TOWARDS the end of 1915 RUTHERFORD MORISON[1] first introduced bipp cream, consisting of one part of bismuth subnitrate and two parts of iodoform made into a paste with liquid paraffin, for the treatment of war wounds At the time he was stationed in England, and most of his cases being late he merely enlarged the wound or abscess cavity and after complete hæmostasis dried the cavity with spirit and applied a small quantity of this paste to the walls He then sutured the wound He was astonishingly successful although, as he admitted, he had acted contrary to the canons of surgical teaching A little more than a year later intermittent irrigation with Dakin's solution, as introduced by CARREL, became the popular method of wound treatment To keep the wound under observation and see the pus washed away made a strong appeal, and, as THOMAS once wrote of other things, it is difficult to cure that " hankering to interfere " But bipp continued to be used by many surgeons although its effectiveness remained a puzzle The bacteriologists have pointed out that in broth streptococci can actually be grown on the paste MORISON was of course aware of this and he repeatedly referred to the fact that the wound discharges contained numerous organisms A full bacteriological investigation of bipped wounds by CHAMBERS and GOLDSMITH[2] at that time showed that aerobic and anaerobic organisms could invariably be recovered but that there was no free proliferation Yet these wounds healed as if they were surgically clean—there was no redness, no induration, and the granulations were vascular and firm Similar observations on the healing of wounds despite a multiplicity of apparently virulent organisms have been made in this war by ORR-EWING, SCOTT and GARDINER,[3] in their bacteriological investigations on wounds treated in plaster

Lately GURD and MCKIM[4] have recorded their successful experiences in the use of bipp for 25 years They explain its action on a physical basis rather than from any special antiseptic rôle of iodoform or liberated iodine They describe it as " curtain drainage " If on a smooth surface such as glass water is poured it will fill the area and stay But if oil is poured on the glass first, water then applied will immediately float off Thus on the walls of the abscess cavity or incised wound oiled with bipp the lymph will not adhere and clot but will continue to flow and there will be a continuous discharge of fresh leucocytes and antibacterial products It is like the paraffined syringe of old for blood-transfusion, where the blood would flow without clotting MORISON and others who use bipp have all commented on the free flow of leucocytic discharge This lymph lavage—a " lymph leech " to prevent any stanching of the lymph outflow—was ALMROTH WRIGHT'S[5] concept of the physiological approach required for wound treatment The drying of the wound with spirit, the use of only a small quantity of bipp to coat the walls (MORISON recommended that no more than two drachms should be used)—these are the rules that must be observed GURD and MCKIM do not agree with the principle of wound suture They make certain by further incisions that the wound tissues are relaxed—especially the fasciæ—and after being lined with bipp the cavity is firmly packed with gauze soaked in liquid paraffin and containing a little more bipp If it is a limb that is wounded it is either splinted or encased in plaster A remarkable feature has been the absence of sinuses and the rarity of sequestrum formation in the compound fractures SAINT[6] has also remarked that little or no sequestration followed in his cases of osteitis thus treated DOUBLEDAY[7] has recently advocated the use of bipp in injuries and abscesses of the jaw In this war there has as yet been no report on the late results of the closed-plaster treatment of compound fractures, but when closed plaster was used in Spain D'HARCOURT[8] and others reported that sinuses and sequestra were definite late problems which still required an answer

There has always been one bogy dangling before the users of bipp—poisoning Tachycardia, delirium or mental aberration, emaciation and signs of bismuth metallism, such as gingivitis, stomatitis and diarrhœa, have been the main symptoms recorded in cases where bipp poisoning was suspected Neither MORISON nor GURD and MCKIM, out of thousands of cases, had any deaths that could possibly be attributed to it It was the misuse of bipp that was responsible for the rare intoxication The latter record seeing knee-joints packed with bipp, and an empyema cavity filled with 6 ounces of the paste With bipp properly used the danger of poisoning is remote, but most surgeons urge special care in children The poisoning symptoms seem nearly always to be due to the bismuth, and gingivitis or stomatitis long precedes any others Washing out the wound with hydrogen peroxide and giving alkalis, GORDON WATSON[9] points out, ensures an ample margin of safety Ten years ago CONNELL and BUCHANAN substituted zinc oxide for the bismuth subnitrate and CONNELL[10] claims that in his ' zipp " the action of bipp has been retained with no risk of toxic symptoms He has employed zipp extensively in the tropics and finds that the problems of maggots and smell in wounds treated in plaster are thus overcome When wounds are plugged with soft paraffin maggots will almost certainly appear in abundance inside the plaster, and although they do no harm (and even good) yet patients justifiably protest Zipp is now being employed in East Africa and further reports will be of special interest HOFFMAN[11] has gone further and sought to add an antiseptic punch to the paste by substituting zinc peroxide for bismuth and adding sulphanilamide powder This he calls " zisp ' He claims that zinc peroxide liberates oxygen and thus deals with the

DIAGNOSIS

The diagnosis of blast injury of the lung is not difficult in the most severe cases Gross shock, out of proportion to the degree of injury, pain in the chest, restlessness, dyspnœa and cyanosis are the main symptoms Blood-stained sputum or free hæmoptysis may be present Bulging of the chest wall, poor respiratory excursion, normal percussion note with perhaps impairment in one locality, distant breath-sounds in all zones and numerous coarse rales or sometimes rhonchi are the main physical signs In milder cases the degree of the symptoms is less, and restlessness and cyanosis may be absent The physical signs are similarly less prominent and added sounds are few or absent X-ray appearances are characteristic They resemble in some measure a patchy pneumonic consolidation to which they are histologically very similar In favourable cases resolution is very rapid, the lung clearing in 4–7 days

The principal difficulties arise in cases where there are gross other injuries, particularly injuries to the chest wall Fractures of the sternum and ribs may confuse the picture Hæmothorax gives a similar picture to blast injury but produces dullness on percussion Pneumothorax similarly may give rise to difficulty, but the hyper-resonant percussion note will point to the diagnosis *Hæmothorax and pneumothorax may both be due to* blast injury Most blast injuries occur in cases which have also contusions or crush injuries of the chest Osborn (1941) contends that since they are so often found together they should be described together But since blast injuries and crush injuries can be studied separately in animals it seems desirable that they should be kept separate as far as possible in human material also, at least until it can be shown that the pathology and treatment are the same

No confirmation is supplied by this series of cases of Osborn's view that blast injury is best marked in the phrenico-costal sinus The severe cases had contusions in the deep parts of the lungs and at the edges The less severe cases had lesions in the thicker parts of the lungs, and showed no lesions in the sinuses With regard to Osborn's "attempt to show that the same lesion may result from a sudden diffuse compression by bombs and mechanical means," it is perhaps a little premature to regard the distinction as only academic

The importance of making a diagnosis of blast injury is great, since rest is of prime importance, and anæsthetics are contra-indicated

SUMMARY

Eight severe cases of blast injury to the lungs without external injury and 2 associated with injury to the chest wall are described in detail, seven less severe cases are also recorded The main symptoms were grave shock, prostration and restlessness, respiratory difficulty and pain in the chest The principal physical signs were bulging of the chest wall, congestion and consolidation of the lungs Bronchopneumonia was a common sequel The radiological appearances are characteristic The treatment consists of heat, morphia, oxygen and plasma-transfusion Blood is only indicated if there is anæmia Chemotherapy should be started as soon as the patient has recovered a little

Five cases showed severe abdominal signs, and two were explored Operation is contra-indicated unless the signs point to a specific lesion A general anæsthetic should be postponed as long as possible The patients should not be moved more than is absolutely necessary

Pathologically, there was gross effusion of blood into the mediastinum due to rupture of capillaries Naked eye, the lungs exhibited patches of intense congestion resembling early lobar pneumonia Histologically, there was (*a*) extensive outpouring of erythrocytes, (*b*) rupture of elastic tissue and capillaries, and (*c*) secondary infection with streptococci causing bronchopneumonia No evidence of fat-embolism was seen

We are indebted to Dr W A Bullough, county medical officer, for permission to publish these cases

Reviews of Books

Bone Graft Surgery in Disease, Injury and Deformi

FRED H ALBEE, M D, F A C S, president of the Int national College of Surgeons London D Applet Century Co Pp 403 35*s*

THE wide use which is now made of the bone graft the surgery of disease, injury and deformity is so mu taken for granted that one is apt to forget the del owing to Albee for his pioneer work Albee's name associated with a fusion operation for spinal tuberculo and he still claims that this method of treatment su plants conservative measures, a view which has nev been shared by British surgeons who find the chief val of the bone graft rather in the prevention and treatmen of ununited fractures and in the ankylosis of joint In this book Albee makes it clear that the success of an graft depends on the perfection of its fit Inaccurac spells failure The ingenuity with which he has devise means of accurately fitting grafts deserves the highe praise and to the young surgeon who wishes to lear bone grafting surgery this book is indispensable Th author has drawn on a lifetime of experience and th methods described cover the widest range As a account of the technique of bone graft surgery the book is supreme It is attractively written and well illustrated

Medical Diseases of War

(2nd ed) SIR ARTHUR HURST, D M, F R C P London Edward Arnold and Co Pp 427 18*s*

THE experience gained in this war since the first edition in January, 1940, has increased this volume by 100 pages Additions include a full account of meningo coccal fever, with the importance of the non menin gitic type stressed; a clear and well-illustrated section on malaria, an addition to the skin section on impetigo, the return of the chapter on amœbic dysentery from the parent volume of 1918, and a review of the "gastric" situation, probably the most important medical problem of this war This is the only existing book on the purely medical aspects of war, and the appearance of a new edition to cover the altered situation is welcome It i to be hoped that future editions will continue to cater for new aspects with further inclusions, even if some omis sions have to be made to keep the work of serviceable compactness For example, shock, resuscitation methods and blast injuries might displace subjects which have not been prominent in this war, such as trench fever and the dramatic type of hysteria We would be sorry to see these last pages go on account of their interest and originality, but economy and price are important points in such a book, which has been invaluable in past war years and should continue to be so

The Medico-Legal Post-Mortem in India

(2nd ed) D P LAMBERT, M D, D T M & H, major I M S London J and A Churchill Pp 113 5*s*

THE previous edition of this little book has evidently achieved the end which the author had in view when it was written, for a second edition now appears with but the slightest alteration in the general matter or arrange ment of the text We previously remarked on the valu of Major Lambert's personal observations on the practica aspects of his subject The book remains an excellent aid to the performance of medicolegal autopsies in India

Plant Science Formulæ

R C MCLEAN, D Sc Camb, F L S, professor of botany University College, Cardiff, and W R IVIMEY COOK, Ph D Lond, F L S, lecturer in the department London Macmillan and Co Pp 203 7*s* 6*d*

THIS is, as stated in the subtitle, a reference book intended for the use of plant science laboratories, inclu ding bacteriology It contains a collection of formul which the authors have selected on the basis of thei experience and that of others as of proved value I addition to those concerned with the fixing, preservatio and staining of material, formulæ for the preparation o the more customary reagents, nutrient media, photo graphic requirements and other laboratory needs ar included Whilst there will naturally be diversity o opinion as to what ought to be *included or omitted* fro such a selection the work should prove a useful additio to the laboratory bookshelf ines and doing work of good quality, are financially very profitable About seventy large firms provide dental services for their employees It is significant of the present low standard of public education in the care of the teeth that a relatively small number avail themselves of N H I facilities

The 15,000 dental practitioners in the United Kingdom vary greatly in the training they have received The committee sent out questionnaires to 11 English dental schools and received 8 replies These showed that the average training in modern prosthetic techniques, orthodontics, radiography, anæsthetics, minor oral surgery and conservative dentistry for children is barely sufficient for the demands of good dental practice, and that the standard demanded of the student varies widely. Thus the numbers of dentures which students were required to complete ranged from 6 to 25 in different schools, and the hours spent weekly in conservation work varied between no fixed number of hours, 20 hours enforced, and 27 hours not enforced In many hospitals there was lack of modern equipment, shortage of tutors and demonstrators, tendency to neglect backward students, and insufficient supervision In addition the status and training facilities for dental mechanics are said to be poor, and the help that dental students receive from these skilled craftsmen is often inadequate The committee promises to publish later a final section on planning for post-war dentistry A remark in their last chapter deserves the attention of our medical planners "The education of medical students in dental matters is deplorably neglected"

COOLING DRUGS AND COOLING CENTRES

In the region of the hypothalamus there are centres which exert such a profound influence on temperature regulation that they have been designated the temperature centres Their identification has stimulated a great deal of research on the physiology of thermal equilibrium and has provided a foundation for hypotheses purporting to explain pyrexia and the mode of action of antipyretics The centres appear to act as a thermostat which in the human subject is set at about 98 4° F but permits of a diurnal fluctuation of approximately 1° F They are themselves sensitive to thermal variations in the fluid that bathes them—if the blood in the carotid artery is made excessively hot the skin reacts as it would to a sharp rise of external temperature Mechanical irritation of the heat centres in experimental animals also causes a rise of temperature, the thermostat readjusts itself to operate at a higher level This curious phenomenon made possible the classical experiments of GOTTLIEB on the pharmacology of the antipyretics He showed that quinine and drugs of the phenazone group abolished this artificial pyrexia, but whereas quinine achieved its effect by depressing tissue metabolism (letting the fire burn low) the newer antipyretics struck at the heat-balancing mechanism, he also showed that these drugs shared with morphine and chloral hydrate a narcotic action on the thermogenic centres, which so upset equilibrium that thermolysis became urgently necessary in order to restore the balance The loss of heat from the skin under these conditions is so brisk that cooling may be compared [illegible] s The hypotheses of early workers receive corroboration from the fact that direct application of antipyretics to the hypothalamus is even more effective than intravenous administration *It is noteworthy that the antipyretic* action of the phenazone group of drugs is seen only when the temperature is raised, they have no action on the normal subject Such was the rage for antipyretics which prevailed in the closing decades of last century that attention was focused almost exclusively on drugs that produced dramatic effects which could be represented by precipitous curves on temperature charts Pharmacologists of the time were slow to elaborate the conception of hypothalamic *centres governing temperature regulation*, but in 1901 HARNACK and his associates showed that picrotoxin, aconitine, veratrine and santonin lowered body temperature in apyrexial animals and they suggested that the action was probably due to stimulation of a cooling centre The discovery that section of the cervical cord abolished the action of these drugs suggested an anatomical relationship to the other temperature-controlling centres, and it was found that a rise or a fall of temperature could be produced by electrical stimulation of various parts of the hypothalamus Localisation was carried a step further by the discovery that lesions of the hypothalamus behind the corpora mamillaria produced a fall of temperature The fact that the cooling action is diminished by hypnotics suggests that the centre responsible shares certain physiological properties with the thermogenic centres The *cooling action is accompanied* by a decrease in oxygen consumption and a fall in the metabolic rate Thus there is a resemblance between the action of quinine in non-malarial pyrexia and the effect of the picrotoxin group of drugs on the normal animal Whether the resemblance amounts to anything more than a superficial likeness it is difficult to say, but perhaps it would be worth while to investigate the antipyretic action of quinine again from this point of view, using the new technique based on the thermocouple and the string galvanometer for measuring skin temperatures

Lately ROSENTHAL,[1] working on rabbits, has confirmed that picrotoxin and aconitine, injected into the infundibular region, have a cooling effect on the animal, the fall of temperature amounted to 4 1° C after 1 μg of picrotoxin and 5 6° C after 0 03 μg of aconitine The cooling effect of the two drugs injected simultaneously was greater than the algebraic sum of the effect of each Arguing from observation of the side-effects of aconitine on the heart rhythm and on the electrocardiogram, ROSENTHAL suggested that the simultaneous disturbances of cardiac action are almost certainly due to stimulation of hypothalamic centres, and therefore that the cooling effect of the drug is also attributable to central stimulation rather than paralysis The grounds for this hypothesis are hardly satisfactory He mentions the side-effects on the heart as evidence suggesting the site of action of the drug, and anticipates the criticism that even the fall in temperature may be due to a toxic action on the cardiovascular system by stating that even when "no cardiac changes" occurred the body temperature fell considerably It should be remembered, however, that normal electrocardiograms may be obtained even when cardiac efficiency has anaerobic organisms, but a fair proportion of his cases nevertheless developed gas-gangrene

---

[1] Rosenthal F E *J Pharmacol* April, 1941 p 305

The curtain drainage action of bipp depends on the paraffin being liquid paraffinum molle must not be used since this will not adhere to the wound walls This fact should be borne in mind in preparing other applications for packing wounds Moreover, LOCATELLI and BOWDEN[12] say that sulphanilamide in an ointment base is inert but in liquid paraffin its full bacteriostatic action is sustained Now that local sulphanilamide is being extensively used it seems therefore that liquid paraffin, or some oil of like consistency, is the rational packing required so as to obtain both the bacteriostatic action of the sulphanilamide and the curtain drainage

CARE OF THE TEETH

DENTAL students, like medical ones, are inspecting their world with a view to alteration and redecoration throughout They have set about it in a mature and workmanlike manner which might be taken as a model for students of all professions, for their Memorandum on the Nation's Dental Services[13] is packed, not with ungrounded enthusiasms or pious hopes, but with solid information obtained by careful inquiry The committee represents five London dental schools (Guy s, London and King's College and both the special dental hospitals) and is working in cooperation with some dental schools in the provinces The memo reviews prewar and present conditions in dental education and in dentistry as a public service and as a career Medical officers of health and school doctors are often enthusiastic about teeth, but otherwise the medical profession has remained curiously apathetic towards public dental services, here shown to be full of serious defects Nor are the public properly educated in the care of the teeth, those attending dental clinics know quite a lot about fillings, but unfortunately public conservative dentistry in the past fell short of the best standards Fillings have so often failed that people have become sceptical, and have in many cases reverted to the view that the dentist only exists to extract teeth Thus the profession is faced with the difficult task of regaining their confidence and re-educating them Some headway is evidently being made, for the numbers of insured people seeking conservative treatment are beginning to rise The cost of conservative treatment, however, is often beyond the means of the uninsured, and it is useless, as the committee points out, to train the public to demand good dental treatment unless the dental services are adequate The care of the teeth should begin before birth with the diet of the expectant mother, it is important that she should be taught this, but it is at least equally important that she should be introduced to the advantages of conservative dentistry before the child is born In some L C C hospitals all antenatal patients are seen by the dental surgeon and invited to have any necessary treatment, and the Eastman Dental Clinic has a staff of women dental surgeons who treat expectant mothers attending the Royal Free Hospital These are exceptions, however, in most antenatal clinics there is no routine inspection by a dental surgeon

The child, before he goes to school, gets little dental supervision beyond that given by the welfare doctor though at a few welfare centres various degrees of dental treatment have been arranged At school he is under the care of the school dental service In 1939, it seems, 69% of the children inspected required treatment, but only two-thirds of these actually received it In most cases dental inspection is only made once a year, and treatment can only be carried out if the parent consents and brings the child to keep the appointment Local authorities usually employ only one full-time dental surgeon for 4000-6000 children The provision is made for the number of children ordinarily accepting treatment, thus in a school population of 5000 only about 2300 children might be expected to accept Good simple treatment can be given by one dentist to about 1450 children yearly, if that number is increased the standard of work suffers proportionately This has been responsible for much of the unpopularity of conservative work in school dentistry, the parents can scarcely be blamed for refusing it in such circumstances, and that it often is refused is evident from the school reports In Kent it has been noticed that many parents, though unable to afford private dental treatment for their children, are yet unwilling to take advantage of the clinics, in Holland, Lincolnshire, caries of the temporary teeth is increasing, and one Nottingham mother who had agreed to send her child overseas withdrew him when she was told that dental treatment was essential Such incidents could have been avoided, perhaps, if the dental profession had resisted from the start any attempt to burden them with more work than they can do with credit Some local authorities, however, are aware of the inadequacies of their services, and are doing their best to improve them On leaving school at 14 the child can get no more dental benefit until he becomes eligible under National Health Insurance at 16 Much ill health and unnecessary loss of teeth result from this gap in treatment at a period of life when dental caries is most rife, and a large part of the work of the school dental service is wasted There is a scheme for dental inspection and treatment of adolescents at Cambridge—apparently the only one in England Coupled with their fine school service this has an opportunity to do invaluable work

As things are, 13 million of our people get N H I dental benefit and 5-6 million children and infants are covered by the school and infant-welfare services; this leaves 24 million for whom there is no regular provision of dental treatment by the state Only a comparatively small proportion of these can afford to pay the full dental fees, yet most dental surgeons serve only this group The dental register has remained stationary at 14,000-15,000 practitioners for the past fifteen years The committee estimate that probably about 34½ million people need regular dental treatment, and that even if each of them visited their dentist only once a year, every dentist in the country would have to see at least eight patients a day There are dental clinics, so called commercial practices, which cater for the poorer sections of the community, these, run on efficient and economical his number includes about 50 medical men and women During the war the society will hold meetings for the discussion of specific topics at various research institutes and the first meeting is to be held at Cambridge on Oct 18, when the subject for discussion will be ' The Evaluation of Nutritional Status ' The meeting starts at 11 A M with an introductory address by Sir Gowland Hopkins This is followed by Drs Harris, Sinclair John Yudkin and G W Robertson on ' Assessment of the level of nutrition in man " , Dr Platt, Dr R H Dobbs and Mr W C W Nixon on " Clinical signs of dietary deficiency ' Drs C Crowther, Green and Hammond on " Nutrition of farm animals " , and then an open discussion

---

[12] Locatelli, A M and Bowden, S *Pharmaceut J* June 7, 1911, p 25

[13] Issued by the Joint Planning Committee of Dental Students Obtainable from the secretary of the committee, Royal Dental Hospital 1s

It has been difficult in the past for the clinician to keep in touch with the advances made by the biochemist, and the agriculturist planning production has rarely been in direct contact with the dietitian who knows the community s needs This new society will bring them together in the same room

ELECTROLYTIC SODIUM HYPOCHLORITE

In the treatment of wounds and burns by the envelope method, Bunyan[1] used sodium hypochlorite prepared by the electrolysis of brine in preference to Dakin's solution or eusol Carey[2] has described a simple apparatus by which the dispensaries of the smallest hospitals could prepare the solution A platinum wire and a carbon rod serve as electrodes The electrolyte is cooled by passing a stream of cold water through a piece of glass tubing suitably bent Failure to prevent the solution heating leads to formation of sodium chlorate The solution used is 18% sodium chloride in water Electrolysis sets free chlorine at the anode and sodium at the cathode The sodium reacts with water immediately to form sodium hydroxide which in turn reacts with the chlorine liberated at the anode forming sodium hypochlorite and sodium chloride The process is continued until about 1% sodium hypochlorite is present If the solution is then diluted twenty times an isotonic fluid results Continuous current must be used , Carey used a trickle charger giving a potential of 12 volts and a maximum output of 1 ampere but this was rather slow The yield depends on the amperage, and the reaction can be speeded up by using a higher voltage The only limit is that set by the heating of the solution, which is also proportional to the amperage

THE RICKETTSIASES

ANYONE who tries to classify and describe the many diseases now known to be caused by rickettsias must face the fact that there are still gaps in our knowledge of their ætiology, pathology and immunology, though on the clinical side there is a fairly broad basis of substantial fact An attempt to summarise the present position has been made by Blumer[3] The rickettsias are a widely distributed group of organisms primarily occurring in insects , possibly they may represent bacteria modified by generations of existence in insects, although it must be remembered that insects are also parasitised by true bacteria which show no similarity to the rickettsias Some include the agents of psittacosis, trachoma, inclusion conjunctivitis lymphogranuloma venereum and conjunctivitis in cattle, sheep, pigs and pigeons among the rickettsias, but at present it seems better to regard these organisms as viruses, for though they have certain morphological and tinctorial similarities to rickettsias there is no evidence that they are in any way associated with insects Some of the rickettsias are pathogenic to man, to their insect hosts and to susceptible animals, while others are apparently harmless symbionts Blumer points out that there are many similarities between the rickettsiases seen in man and animals Thus all rickettsial infections are transmitted through vectors—lice, ticks larval mites or fleas A given rickettsia, however, may be transmitted by more than one genus of vectors or by different vectors of the same genus In some rickettsiases there is a primary lesion at the point of inoculation , this is true of fievre boutonneuse, South African tick-bite fever and Japanese river fever or tsutsugamushi disease but not of others All the rickettsiases tend to present clinical resemblances in a sudden and often severe onset, a tendency to terminate by crisis, sometimes skin eruptions of a hæmorrhagic type and often involvement of the central nervous system Recent observations suggest that many rickettsial infections involve the lungs setting up a pneumonitis or interstitial pneumonia The essential pathological feature common to all rickettsiases is an involvement of endothelial cells In the blood-vessels this involvement causes proliferative and degenerative changes that are chiefly responsible for the skin eruptions and hæmorrhages as well as for the changes in the central nervous system. It is curious that despite the frequency of typhus epidemics there is still no agreement as to the leucocyte changes in this disease, though there is evidence to show that a polymorphonuclear leucocytosis is more common than in any virus infection In one important point exanthematic typhus shows a similarity to many virus diseases—in the occurrence of inapparent infections In a Belgrade epidemic it was found that the serum of 13% of a group of apparently healthy people gave a positive Weil-Felix reaction in dilutions ranging from 1 100 to 1 800, and only one of the group had previously suffered from clinical typhus fever The blood of some of them was still infectious for guineapigs

OSTEOMYELITIS OF THE SPINE

Lannelongue[1] first described a case of osteomyelitis of the spine in 1879 but the difficulties of diagnosis and treatment have yet to be overcome Three main clinical types have been described according to the degree of virulence of the disease process In the fulminating cases the picture of septicæmia is uppermost, local signs being masked by the severity of the general symptoms Blood-culture is almost always positive, and few reported cases have recovered The subacute type is marked by early abscess formation in addition to the general signs of infection, and symptoms referable to the affected vertebræ are usually evident Symptoms suggestive of an infection of the urinary tract are constantly seen when the dorso-lumbar region is affected, and may give rise to errors in diagnosis Bony changes on X-ray examination are not seen until the third week, although radiography may be of value in disclosing deeply lying abscesses as early as the seventh day of the disease The chronic type is more rare, but is of particular importance owing to the danger of confusion with Pott's disease. In differentiation age, rate of progress and the radiological appearances will help Osteomyelitis mainly affects adults, tuberculous caries mainly children , even in the chronic type osteomyelitis progresses more rapidly than tuberculosis , radiologically, osteomyelitis destroys the intervertebral disc earlier and spreads more quickly to the adjacent vertebræ Regeneration of bone is seen during the healing stage of tuberculosis, but this is more definite in osteomyelitis and usually goes on to new bone formation and even bony union The three types of osteomyelitis were clearly differentiated by Butler, Blusger and Perry,[2] who described a case which was unaffected by sulphapyridine but steadily improved on sulphathiazole Holmberg[3] has described seven cases,

diminished to the point of circulatory collapse Furthermore, the rapid onset of hyperglycæmia which ROSENTHAL shows as an accompaniment to the fall of temperature after aconitine suggests a sympatheticomimetic action rather than vagal overactivity, indeed, a fair interpretation of this phenomenon is that the sharp fall of temperature stimulated the adrenal to staunch the flow of radiant heat by means of vaso-constriction, and that the accompanying hyperglycæmia reinforced this mechanism, which aimed at restoring thermal equilibrium The well-known antagonism between picrotoxin and the barbiturates is illustrated by ROSENTHAL's experiments, the cooling action of picrotoxin was practically abolished by the simultaneous injection of phenobarbitone The fact that these two drugs cancel one another out in the pharmacological sense rather than by chemical union is confirmed by the observation that either of them alone is capable of producing a fall of temperature Moreover, the masking effect of the phenobarbitone on the picrotoxin cooling phenomenon proves that this cooling action must be the result of stimulation of a separate centre and not merely the consequence of paralysis of heat-production centres One of the dangers of being under the influence of narcotics is that these drugs produce increased susceptibility to changes in temperature in one's surroundings HERRMANN[2] has shown that sub-hypnotic doses of depressants to the central nervous system, including morphine, pentobarbital and paraldehyde, cause loss of control over temperature regulation, and the toxicity of these drugs was found to be increased by low environmental temperatures These results, obtained in animals, may have some therapeutic application in the management of patients who are allowed to go about while receiving hypnotic drugs—epileptics, for example, who are taking several grains of phenobarbitone daily Furthermore, a few years ago we were assured by "the trade" that every sailor knows that rum keeps the cold out, and pharmacologists were bewildered by this contradiction to their own teaching Certainly if HERMANN's results are applicable to the methane series of narcotics generally rum is more likely to let the cold in, though the sailor with rum inside him may not care either way

So far the drugs which have been shown to possess this cooling action are also noteworthy for their high toxicity Picrotoxin is finding its way back into therapeutics merely as an alternative to strychnine in the treatment of barbitone poisoning, but even here the drug is rightly classified among the desperate remedies Aconitine once enjoyed a considerable reputation as a diaphoretic and antipyretic, but a well-founded prejudice against cold sweats and increasing recognition of its harmful effects led to its abandonment by the physician In any case, such a drug could hardly be expected to hold its own when aspirin was made available Perhaps the main value of the recent precise work on cooling drugs is that it justifies a search for new substances—possibly synthetic products—with a pharmacological action on the hypothalamus comparable to that of the picrotoxin group of drugs, and yet having that margin of safety which POULSSON used to call ' latitude of therapeutic action "

Annotations

RADIOLOGY AS A CAREER

THE events of the last two years have shifted many medical careers into other channels and have raised doubts about the prospects after the war of this or that branch of medicine There is however little doubt that there will be a shortage of radiologists unless newly qualified men turn their thoughts now in that direction The Ministry of Health is prepared to enrol in the Emergency Medical Service radiology house surgeons at selected hospitals in London and the provinces Applicants must satisfy the deans of their medical faculties or schools that they intend to take up radiology and are prepared to enter for a diploma in medical radiology at the termination of their course of study The selected hospitals will be so situated that attendance at course of instruction will be practicable, and successful applicants will be required to undergo the appropriate course of instruction, paying the necessary fees Applicants must have held a house appointment at a hospital for at least six months, and preference will be given to those with longer clinical experience The salary will be at the rate of £200 a year with an additional £100 for board and lodging if the officer is required to live outside the hospital Applications should be made (through the deans or group officers) to the Director of Establishments, Ministry of Health, Caxton House, London, S W 1

FOUNDATION OF THE NUTRITION SOCIETY

NUTRITION, more than almost any other subject, concerns scientists of widely different training and outlook The clinician has always been concerned with dietetics, and in the last 25 years he has come to recognise more and more diseases caused by nutritional deficiencies The study of the digestion, assimilation and metabolism of foodstuffs occupies many physiologists, and biochemists are engaged more on nutritional problems than on any other single branch of their science Economists, sociologists, public-health officials, agriculturists and chemists too are all deeply concerned with the science of nutrition, but there has hitherto been no common meeting ground for discussion Even the Biochemical and Physiological Societies and the nutrition panel of the Society of Chemical Industry include only a minority of those who are interested in nutrition Before this war workers engaged on nutritional research had often discussed the desirability of founding a scientific society that would embrace all who had a genuine interest in the various branches of the subject A year ago an informal group composed of about twenty representatives of the main laboratories working on nutrition started to meet about once a month But it soon became apparent that even in war time it was desirable to have meetings that were more formal and had a much larger attendance Representatives of the institutes interested therefore met at the Royal Institution and decided to form the Nutrition Society, with the following provisional committee Sir John Orr, M D, F R S, Rowett Research Institute (chairman), John Hammond, F R S, School of Agriculture, Cambridge (vice chairman), Leslie Harris, D Sc, Nutritional Laboratory, Cambridge (hon secretary), A L Bacharach, Glaxo Ltd (hon treasurer), Harriette Chick, D Sc, Lister Institute, Ethel M Cruickshank, Ph D, School of Agriculture, Cambridge, H H Green, D Sc, Veterinary Laboratory, Weybridge, Prof H P Himsworth, M D, University College Hospital, Prof A St G Huggett, M B, St Mary's Hospital, Franklin Kidd, D Sc, Food Investigation Board, S K Kon, D Sc, National Institute for Research in Dairying, B S Platt, M B, Medical Research Council, H M Sinclair, D M, Department of Biochemistry, Oxford About 230 scientists who are or have been working on nutrition have been invited to become original members,

In England Now

Running Commentary by Peripatetic Correspondents

HERE must be quite a number of people who move in les far higher than I have ever had hopes or wishes of aining who get a lot of quiet fun out of the present glo-Soviet accord Some of us humbler ones have many years tried to persuade our fellows that the abitants of the U S S R were not barbarians We tried to disillusion those of our colleagues who clung the belief that savages with whiskers, blouses and -boots, bloody in deeds and crude in ideals, were the ers of the real U S S R We had tried to tell our low-workers in science and medicine that we did ill vice to our calling in closing our minds to the remarkle contributions to knowledge made by the workers in Soviet Republics Now, I and those others who ve striven to obtain some recognition for the Russian ntributions to science, to medicine, to art and literature ve the laugh of our fellows It is almost pathetic to low the painful efforts of our journals to fall into line an inglorious unanimity for praising Russian scientific hievements But to one who has striven in the days that stupid blindness of British orthodox outlook wards these things, the whole business seems pitiful yond the last dreams of cynicism It is not a laugh at one gets from these reflections—it is a heart-wrung ar and a soul-felt prayer Are we all so small that, cause some of us by background, traditions, possessions privileges disliked the Russian political regime, we ncied we could despise the scientific advances made by ese people ? Surely the world has been disillusioned now That the military organisation of the U S S R is surprised our wretched Blimps by its efficiency in arfare is a small thing To surprise a Blimp is a trivial tainment But that science, in the person of thousands British scientific workers should be surprised, now at it has come to realise the advances made in the viet Union, is surely a matter for regret It is a pitiful tisfaction to indulge in that lowest form of asserting e's justification by saying " I told you so " but at mes it is difficult to avoid doing it

* * *

Cecil Houses—only three now instead of five—have eld by their bargain women still find there tea and read-and-butter night and morning, a clean bed, a hot ath, facilities for washing clothes and the use of a warm ay sitting-room, for a shilling a night with no questions sked But for the first time since the original house as opened in 1927 the trust has ended up the year with a alance on the wrong side Once the foundation costs re paid the houses are normally self-supporting , but owadays rates, gas, light, fuel and provisions have all isen in cost , blackout materials have been a recurrent xpense as blast and broken glass take their toll of them The show house in Boswell Street was an air-raid casualty nd has had to be closed until reconditioning is possible The Kensal Road house is not easily reached in the lackout , the women hesitated to cross the dark canal ridge, and the reduction in numbers made running costs too heavy to keep open It has been rented to the Ministry of Pensions during the war The remaining three houses, though knocked about, have been able to carry on in spite of adventures in which they lacked gas, water and light, or contended with broken windows No-one was hurt in these raids, but first-aid repairs to the houses have been costly

Yet the houses are needed more urgently than ever They provide for many women their only security, and in the circumstances it has become impossible to restrict the time each one stays Some have settled in as permanent guests, ensuring their lodging for 7*s* a week , others are temporary guests seeking lodgings between jobs, or women staying in London to catch sight of relations or friends in the forces as they pass through , others are themselves on leave from the Services Nearly all are in work , they come back in the evening to cook their meals in the communal kitchen and exchange gossip of the day's doings before adjourning to share the sitting-room fire or —the younger ones—to enjoy dancing and music in a downstairs room Before the war the houses were shut during the day, but now this regulation is relaxed , the houses are open in daytime, and those on leave can rest or read there A fund is kept for those who cannot afford to pay the shilling but it is rarely drawn upon , and there is a wardrobe for fitting out those who need them with clothing, hats and shoes Women can bring their young children, paying 3*d* for a cot beside the bed , mothers and children occupy a separate dormitory, so that a crying child will not disturb the other guests

To prevent the danger of spread of vermin or disease the beds are inspected every morning , if vermin or traces suggesting disease are found, bed and bedding are sent to a disinfecting station The occupant of the bed, next time she comes, is taken aside and asked in the first case, whether she is willing to go to a cleansing station, and in the second whether she will attend a doctor free of charge She rarely declines but if she does it is explained to her that she cannot be admitted because of the danger to other lodgers

* * *

The worst thing about Army doctoring is the little medicine in it The work of an R M O is invaluable and it couldn't be done by anyone else , but professionally it's unstimulating routine and clinically it hardly exists Men must be kept healthy if they misbehave by becoming sick off they go to hospital In civil life the " diagnosis, ill , treatment, hospital " sort of practice was exceptional In the Army, and for the best of military reasons, it is the rule Now, the prevention of disease and promotion of health is a fine philosophy, and one to which I fully subscribe Until the Golden Age arrives, however, it will still be useful for doctors to know quite a lot of medicine Many of us in the Army, it seems to me, are in danger of disuse atrophy, of becoming stale and rusty, of forgetting the little that was acquired at such great pain, of finding ourselves on demobilisation with a necessary job done but worse doctors than we were on enlistment This is a problem that wants tackling, and not by cosy planning but straightaway Postgraduate education has never been a highlight of British medicine , it was never so badly needed as now The answer seems obvious In this country the hospital is the centre of medical education Although this is strictly speaking not a military responsibility at all, the military hospital could take over this function for the military doctors and district it serves Clinical meetings are already fairly common though there is plenty of room for expansion Much more to the point, one hospital I know of organises regular week-end schools The specialists do their stuff and the local M O s at the least enjoy it Half lecture, half clinical, the two days are packed with streptococcal fevers, resuscitation, eyes, feet, vitamins, Vincent's angina, effort intolerance, mental deficiency, gas, oxygen, running ears, scabies, and so on There's not much time for digestion in this rather Stakhanovite sort of effort but that happens afterwards, it is hoped Schools like this, and on a larger scale, would be a great help

The Army Medical Department itself issues excellent bulletins and leaflets from time to time, and courses are organised on many military subjects Why not on just ordinary medicine and surgery ? And run perhaps by the universities on the lines of the " intensive " weeks at Hammersmith ? Of course everyone concerned is terribly busy Probably the most useful measures of all would be a wider sharing of G D O appointments at the hospitals and part-time attachments to the hospitals But these involve all sorts of issues on which I haven't the knowledge to speak

* * *

Twice I have decided that this war really has gone on long enough—once on the awful morning when there was no marmalade for breakfast, and again at the week-end when the family joint was beef and there was no mustard Being bombed in one's hospital or being called out as a member of a mobile unit to attend to air-raid casualties was all in the day's work and somehow rather impersonal , but these other matters brought the war very near home Fortunately neither crisis lasted long , marmalade reappeared next morning and the mustard shortage was definitely overcompensated, since within a week our maid had produced a small tin, my grateful grocer patient a large tin and my sister turned up on leave with yet another large one

This " grateful patient " of mine rather worries me I had not seen him since well before the war, indeed I one of which he suggests was influenzal He maintains that the rarity of osteomyelitis in the vertebræ when compared with the long bones is due to a local immunity of the vertebral red bone marrow - He points out that a focus of infection is often present and mentions that Fraenkel demonstrated bacteria in some patients who had died from infections although there had been no local symptoms during life Apart from chemotherapy, whose value in this condition has yet to be confirmed, treatment consists of immobilisation in a plaster bed or jacket in the later stages, with drainage of abscesses and (rarely) with removal of free sequestra

GROWTH OF THE OVARIAN FOLLICLE

As follicles grow they first sink into the ovary, and as they increase in size and develop thecæ and an antrum they move again to the surface According to Strassman,[1] who has published a full account of his laborious research on follicular growth, the downward growth of the small follicle is due to the lesser resistance of the interior of the ovary as compared with the ovarian cortex On the other hand the return of the follicle to the surface is due to eccentric growth of the theca interna, which develops a thick growing cone, overlaid by a thin and non-resistant layer of theca externa, towards the surface of the ovary On the opposite pole of the follicle the theca interna is thinner but is overlaid by a thicker theca externa The theca interna cone has a definite tropism to the nearest point of the ovarian surface, the granulosa cells can push their way more easily among the soft cortical cells than they can towards the deeper parts of the ovary This conception of the way in which the follicle moves is different from older views which related the return of the follicle to the ovarian surface purely to mechanical growth It will be interesting to discover whether the theca interna also plays an active rôle in ovulation, rather than the passive one which is generally ascribed to it

PLANTAR RESPONSE IN HEALTHY INFANTS

THERE are said to be seventy articles in eight languages on the plantar response in infants, but Dr Myrtle McGraw[2] of New York has usefully made the number seventy-one in a study of 75 normal children ranging from the newborn to the five-year-old Repeated examinations were made at monthly or longer intervals and records of 1011 observations were obtained, of which 74 were on motion-picture film and 937 were written protocols The stimulus consisted of a light stroke with a toothpick along the lateral aspect of the sole and across the metatarsal arch to a point proximal to the great toe Notes were made of the reactions observed, including movements of the leg as well as flexion and extension of the toes The types of response elicited could be broadly divided into three groups In the younger children, and characteristic of the first four months of life, was the mass-reflex Here dorsiflexion of the toes is accompanied by movements of the entire leg—contraction of the flexor muscles at the hip, knee and ankle as well as dorsiflexion of the toes The most consistent part of the response is a sudden, total withdrawal of the whole extremity Next comes the transition phase the speed of withdrawal is diminished and consists principally of an abductor response of the leg Plantar flexion of the toes is more common, although there is considerable variation in the movement of the toes and the great toe This transition phase develops slowly and is predominant by the end of the first year The third phase, termed the "segmental reflex phase," was common to all the children after the age of two and a half years The response to plantar stimulation becomes increasingly restricted until it consists of movements of the ankle and toes only Ankle movements are flexion, inversion eversion, and the common response of the toes is pl flexion, movements being much slower than t characteristic of the mass reflex In a few childre type of plantar response was correlated with the de ment of erect locomotion, and in 26 out of 33 the of the third phase, the segmental reflex phase, c about the time of deliberate walking Althoug most children this third phase had been reache three and a half years, dorsiflexion of the toes elicited occasionally as late as four or five years these later age groups, however, such extensor were not accompanied by the mass withdrawal rea characteristic of the newborn infant

SYPHILIS OF THE LUNG

THE clinical diagnosis of acquired pulmonary syp is never easily made This is due partly to the propen of syphilis to mimic other conditions and partly to rarity with which treponemata can be demonstra before and after death Pulmonary manifestations unusual in the secondary stage When they do oc they resemble, in the bronchial mucous membrane, lesions found higher in the respiratory tract, a lo pneumonic form has also been described at this sta It is, however, in the tertiary stage that the parenchy of the lung is most often involved and the standa works on respiratory medicine portray distinct path logical guises in which the infection appears Pneumon (sometimes with a lobal distribution), an indurative fibrotic form, and gummata either large or miliary a all recognised Pearson and De Navasquez,[1] from pe sonal observations and a study of the literature, ha lately sought to harmonise these multiple manifestatio into the changing sequence of a single process Th regard an acute interstitial pneumonia as the startin point, this may organise to produce a diffuse sclero or may undergo necrosis with gumma formation T differences encountered, therefore, become one of degr and of time rather than of a fundamental type of reactio They view the whole process of parenchymatous pu monary syphilis as dependent on a disease in the media tinum, and of all the organs that can act as a pivot po the aorta takes pride of place Thus Carrera[2] fou syphilitic infection in the heart and aorta of all the cases of lung syphilis that he studied and the same w true of the case reported by Pearson and De Navasqu The association is too constant to be solely due to chan even when allowance is made for the high incidence aortitis in syphilis, and it is now becoming axiomatic t the diagnosis of pulmonary syphilis, either during or after death, is open to question unless there is fou in addition, reasonable evidence of specific aortitis of aneurysm The criteria for the successful clin recognition of parenchymatous pulmonary manife tions of acquired tertiary syphilis can be summar thus (1) an anomalous history of pulmonary di that may be brief or may be measured in months or e years, (2) the exclusion, by recognised methods, of ot causes for the lesion, especially tuberculosis, (3) presence of syphilis in other organs or the stigmata past infection, (4) positive serological findings, (ready response to antisyphilitic treatment particul when revealed by serial radiograms, and (6) evide of mediastinal disease, especially aortitis and aneury Appraisal of all the evidence in the light of these po will do much to prevent the diagnosis of lung syph from resting on an insecure foundation, convers Dr Clark's case reported in this issue comes as reminder of how sometimes the spirochaetal origin an obscure pulmonary illness can confidently inferred invoked to cover up Ministerial deficiencies by unintelligent uniformity Major LLOYD GEORGE heartened the House by his sympathetic and cheering reply From Nov. 17 he said, the domestic fat ration will be increased temporarily from 8 oz to 10 oz per week and the sugar ration from 8 oz to 12 oz He hoped the dried fruit position would be much better He wanted to encourage the provision of canteens for heavy workers and to allocate to them substantially increased quantities of some food Catering establishments for essential workers would be treated in the same way. In the heavy industry canteens it was hoped to double the meat ration and to treble the sugar allocation In trades where the work was not so heavy meat allocation would be increased by a half and the sugar allocation doubled He hoped also to make available increased supplies of bacon and ham cooking fats, processed eggs, and cheese

---

[1] Strassman E *Amer J Obstet Gynec* March, 1941, p 363

[2] *Amer J Dis Child* June, 1941, p 1215

[1] Pearson, R S B and De Navasquez S *Guy's Hosp Rep* 1 88, 1

[2] Carrera, J L *Amer J Syph* 1920, 4, 1

Sir E GRAHAM-LITTLE said the diet of the heavy worker was better a hundred years ago when he had eaten wholemeal bread, milk and green vegetables instead of meat and white bread He could not understand why the Government did not make our national wholemeal loaf compulsory Today it is not even in general supply Dr EDITH SUMMERSKILL thought it was unfortunate that malnutrition was not accompanied by a rash and reminded the Minister of Food of the increase in tuberculosis among young women She pointed out that the expectant mother is expected to sustain two lives on one ration

Plans for Tomorrow

Speaking in the debate on the war situation Dr HADEN GUEST said that the problems of the future were already reaching back to us in the present One tremendous problem would be health in Europe and in this country. So far our health had been good but the report on public health in Scotland and other information showed that war conditions had caused an increase in tuberculosis Our rationing and living and working conditions were good yet in Glasgow there was an increase of 10% in tuberculosis due to the strain of war which would be multiplied in Europe and in the Soviet Union Dr Guest acclaimed the plans made at the conference of allied nations to send help and food to Europe as soon as hostilities stopped but felt that Parliament might in principle go a little further It would give heart to all people of good feeling if we began now to make plans on a world-wide scale to deal with the world health at the end of the war

Wives without Children

On Sept 30 Captain C C POOLE asked the Secretary of State for War whether he was aware of the poverty and hardship suffered by many wives and children of members of the Forces, and why these dependants were placed in a less favourable position than the dependants of those who remain in industry Sir ROBERT GOWER also asked him if he was aware that experienced social workers reported that numbers of families of serving men find it impossible to manage on the present scale Captain MARGESSON referred both members to the PRIME MINISTER's reply to another question when he said that, while the recent revision of family allowances of junior officers was the first general improvement in the emoluments of officers since before the war, the family allowances of other ranks had been improved several times since that date and the pay of all N C O s and men increased last year by 6*d* a day war pay But he was examining the suggestion that some of the families of other ranks are experiencing hardship and difficulty and he would make a further statement as soon as possible

In this parliamentary backchat the emphasis is rightly laid on the family, for it is the soldier's wife with a brood of children who is having the hardest time today Even with schools and day-nurseries it is difficult for her to get really remunerative work, and yet give her children the care and attention they need But the wife without children can supplement her allowance with a well-paid job—indeed the Government is anxious that she shall volunteer to help build a spitfire or a tank Or she may join one of the women s services where she not only gets her board, lodging and pay but also receives an allowance, contributed jointly by her husband and the Government With plenty of work for everyone and not enough money to give as much as we would like to the soldier s children should we not think again about the distribution of our pennies and consider making motherhood and not marriage the qualification for an allowance ?

QUESTION TIME

Medical Advisory Committees

In answer to a question from Sir ERNEST GRAHAM LITTLE the Minister of Health said that none of the members of his medical advisory committees receives remuneration for their services Their membership is as follows —

Central Medical War Committee—H S Souttar F R C S (chairman) H Guy Dain M B , J W Bone M B H W Pooler, M B Colonel A H Proctor, M D Prof P M F Picken M B W E Thomas L R.C P E , E A Gregg L R C P I D G Greenfield, F R C S P Macdonald, M D , J C Matthews M D Prof A H Burgess F R C S J A Brown M D ; G E Elkington F R C S F W Grant L R C P E F Gray, M.B , J M Johnstone, M B , Sir Kaye Le Fleming M D S A Winstanley M B , Charles Newman M D , Sir Charles Wilson P R.C P Sir Girling Ball F R C S Sir Alfred Webb-Johnson P R C S Prof W Fletcher Shaw, P R.C O G T G H Shore M D Russell J Reynolds M B D Embleton M B J D M. Committee on Tuberculosis—Sir Percival Hartley, M D (chairman) J H Harley Williams M D J B McDougall M D D A Powell M D G T Hebert M D N Lloyd Rusby B M J Ferguson M B W Allen Daley, and Norman F Smith M D

Shelter Health Committee—Lord Horder (chairman) Miss Creswick Atkinson R.R C Sir Wyndham Deedes R C Cox M Inst C E and Colonel P G Stock F R C P

C.M W C and Home Guard

Replying to a question Mr BROWN said that to avoid undue interference with the medical organisation of the locality Army Council instructions provide that no medical practitioner is to be enrolled in the Home Guard unless previous permission has been given by the local medical war committee It is open to any practitioner aggrieved by the Committee s decision to communicate with the C M W C under whose general directions the local committees act If he is dissatisfied with the conclusion of the central committee and wishes to make representations to me I shall of course be prepared to consider them. There is no representative of the Home Guard as such in the membership of the central committee but an observer attends on behalf of the War Office

Medical Man-power

An interim report has been received from the Shakespeare Committee and action is being taken on the recommendations These include suggestions for the establishment of regional committees to promote the maximum coöperation between civil and service medical establishments the continued recruitment for the time being of medical officers for the Forces at the rate at which they are now being recruited, the compilation of particulars of bed accommodation and staffing for all civil hospitals and measures to secure greater mobility of resident medical staffs as between one hospital and another (Mr BROWN replying to Sir FRANCIS FREMANTLE.)

Alien Doctors

Under a recent order an alien doctor who fulfils the other necessary conditions may be placed temporarily on the Medical Register if he is to be employed as an assistant to a British doctor in private practice The employment is in each case subject to the approval of the Home Secretary (Mr BROWN replying to Miss E. RATHBONE.)

Milk in Schools

In answer to a question addressed to the President of the Board of Education, Mr J C EDE stated that in May, 1941, had forgotten all about him till the other week when one of these minor food crises which are continually cropping up reminded me of him I hesitated a long time Could I really have the brass neck to call on him, inquire after his health and gradually lead up to the major question of whether he could help me ? In the end the domestic shortage of biscuits won the day—I took the plunge and the next time I was in his neighbourhood boldly entered his shop I am sure he saw through me at once, but he played his part like a gentleman, and a weekly call now seems part of the routine of a visit to town The result is that I am never so popular at home as on the day of my London visit, whence I now return with a medley of biscuits, jellies, tinned fruit blancmanges or lime juice—all those little extras utterly unessential to life but so delectable to the palate of a child Actually my youngsters do not do too badly, as I usually manage to produce a weekly ration of chocolate from the enterprising steward of one of my hospitals who keeps a secret, if small, store of confectionery

Another minor shortage which is threatening to modify our social habits is the scarcity of sherry I must confess to a certain disappointment when twice within a week I was invited out to dinner and both times had to sit down to a completely teetotal meal, and when this was followed by an invitation to coffee, because " sherry is so difficult to get these days," I felt that life really was becoming rather hard But when I tackled my own wine merchant he said he could let any of his customers have half a dozen bottles of sherry a week, and if any *Lancet* reader has the price of half a dozen I will reveal his name I shall expect a non-teetotal dinner in return

* * *

There have been a lot of letters in the *Lancet* lately about the treatment of venereal diseases in the Forces It is all very well the military saying that opportunities are given for treatment, when necessary even by doctors who are not in uniform in establishments administered by civilian authorities I know that most commanding officers do their best for their men, but there is still the idea that a man with v d is a defaulter There is no point in arguing about this ; it is certain that he is also sick and that to deprive a man with gonorrhœa of his treatment because his unit is going on manœuvres is not only unfair to the man but military shortsightedness, for it may lead to his permanent invalidism and loss from his unit If the military really think (which I don't) that punishment has a prophylactic effect let it be given when he is cured and let his cure be expedited in every way

There is another side to the question which seems to be almost completely neglected There are concentrations of men in isolated rural districts which have only a very rudimentary public-health service The soldiers get their treatment (and perhaps their punishment) without difficulty In the case of their contacts the situation is reversed The incidence of untreated female v d in certain rural districts is truly horrifying It may be said that medical men as scientists have no business to be horrified, but what horrifies me is the attitude of local health authorities which refuse to recognise the very existence of the problem

* * *

My wife has remarked that it's all very well my being high falutin' but what about infant's food Admittedly we have an allergic daughter (Freud never explained why doctor's daughters are allergic) but the difficulty today in obtaining any artificial baby-food seems disproportionate No doubt brands of artificial food are more numerous than the physiological needs of infants demand, but something should be done to standardise the position There are times when we cannot buy any brand of cereal food in a market town of 12,000 inhabitants for a year-old child Surely the manufacturers could agree among themselves and produce several standard products suiting various age-groups and requirements and thus remove at one blow present distribution difficulties and the artificial complexity of an advertisement-controlled market While we are on this subject, why should not oranges be only purchasable on production of an infant's ration card ? That would do more good to our war effort than using them as a diluent for gin in an A T S subaltern's cocktail at a Thames-side inn Yes, I can hear you asking what I was doing there The answer is that I would not drink a Bronx if you stood me one I like my alcohol recognisable

Parliament

FOOD PRODUCTION AND DISTRIBUTIO

CONVERSATIONS everywhere in England now turn of
and eagerly to food Our legislators also take at least
administrative interest in the topic for last week it
the subject of debate in both houses In the Lord
Sept 30 Viscount BLEDISLOE took as the text of
appeal for more feeding-stuffs for livestock the
bulletin (No 3) on " Home Production and U
Feeding Stuffs in War " He asked whether the Gov
ment were in general agreement with its arguments
deductions ; and whether in the light of them t
contemplated amending their estimate of the num
of livestock, especially poultry, we could maintain

The bulletin urges that the Government's p
extend our acreage under wheat at the expense of c
grown for livestock, with an inevitable shrinkage of
stock and their products Lord TEVIOT commen
the words of Dr Norman Wright[1] to the Governm
and urged that farmers should be allowed to keep at le
10% of their wheat for their animals

Lord DAWSON said that experts did not always sp
with a single voice and that he thought the Minister
Food, acting on misleading data, had over penalised t
hen, since it was a competitor for human food But t
intensive hen was a very remarkable creature, produc
180 eggs a year, and second only to the cow as a convert
of feeding-stuff Milk and eggs were a very tower of nut
tion strength and especially useful in the preparation
light foods for workers beginning to get weary in min
and weak in their digestions It was right that childre
and invalids should have priority but we also needed egg
to keep our active population fit and well, and housewive
a forcible group when they got going, were demandi
that the production of the egg, an important appanage
their homes, should be maintained It was importa
Lord Dawson continued, that we should produce prote
rich food for our animals and hens, not next year, b
within the next two or three months In the man
facture of acetone there was a by-product contai
large quantities of protein which had been used to fe
pigs and other animals in the last war, but at prese
was being wasted There was also a synthe is
protein of high value, made in part of dried yeast, whic
he believed, was ripe for manufacture on a large scal
He urged the Ministry of Food to hustle this on Th
was being made with sheep cheese, and a higher nutriti
value was to be obtained from the ewe in terms of chee
than in terms of mutton Lord Dawson also plead
that tuberculin-tested herds should be protect
Certain food officers did not seem to realise that th
cows had been gathered together for years past and
anything happened to the herds it would take years
undo the evil Yet an order had been issued to reduce
quantity of tuberculin-tested milk by 200 gallons a w
by Oct 18 It was ironical for such a thing to hap
when concern was being felt at the increased incidenc
tuberculosis, and he felt there must be some mista
We should endeavour to stay the down-grade proces
the production of milk, for production is like virtue
is easy to make a reputation, still more easy to lose
and once lost it takes a long time to rebuild T
Marquess of CREWE declared that the Ministry of F
was an expedient, not an institution, but that manure
the pivot of British agriculture

The Duke of NORFOLK in his reply said that
Government was in agreement with the arguments
not the deductions of the I C I pamphlet It was t
that we could not live by bread alone, but it was also t
that we could not live by meat and eggs alone L

ivoked to cover up Ministerial deficiencies by unintelli-ent uniformity. Major LLOYD GEORGE heartened the House by his sympathetic and cheering reply From Nov 17, he said the domestic fat ration will be increased emporarily from 8 oz to 10 oz per week and the sugar ation from 8 oz to 12 oz He hoped the dried fruit position would be much better He wanted to encourage the provision of canteens for heavy workers and to allocate to them substantially increased quantities of some food Catering establishments for essential workers would be treated in the same way In the heavy industry canteens it was hoped to double the meat ration and to treble the sugar allocation In trades where the work was not so heavy meat allocation would be increased by a half and the sugar allocation doubled He hoped also to make available increased supplies of bacon and ham, cooking fats, processed eggs, and cheese

Sir E GRAHAM-LITTLE said the diet of the heavy worker was better a hundred years ago when he had eaten wholemeal bread milk and green vegetables instead of meat and white bread. He could not understand why the Government did not make our national wholemeal loaf compulsory Today it is not even in general supply Dr EDITH SUMMERSKILL thought it was unfortunate that malnutrition was not accompanied by a rash and reminded the Minister of Food of the increase in tuberculosis among young women She pointed out that the expectant mother is expected to sustain two lives on one ration

Plans for Tomorrow

Speaking in the debate on the war situation Dr HADEN GUEST said that the problems of the future were already reaching back to us in the present One tremendous problem would be health in Europe and in this country. So far our health had been good but the report on public health in Scotland and other information showed that war conditions had caused an increase in tuberculosis Our rationing and living and working conditions were good yet in Glasgow there was an increase of 10% in tuberculosis due to the strain of war which would be multiplied in Europe and in the Soviet Union Dr Guest acclaimed the plans made at the conference of allied nations to send help and food to Europe as soon as hostilities stopped but felt that Parliament might in principle go a little further It would give heart to all people of good feeling if we began now to make plans on a world-wide scale to deal with the world health at the end of the war

Wives without Children

On Sept 30 Captain C C POOLE asked the Secretary of State for War whether he was aware of the poverty and hardship suffered by many wives and children of members of the Forces, and why these dependants were placed in a less favourable position than the dependants of those who remain in industry Sir ROBERT GOWER also asked him if he was aware that experienced social workers reported that numbers of families of serving men find it impossible to manage on the present scale Captain MARGESSON referred both members to the PRIME MINISTER's reply to another question when he said that, while the recent revision of family allowances of junior officers was the first general improvement in the emoluments of officers since before the war, the family allowances of other ranks had been improved several times since that date and the pay of all N C O s and men increased last year by 6*d* a day war pay But he was examining the suggestion that some of the families of other ranks are experiencing hardship and difficulty and he would make a further statement as soon as possible

In this parliamentary backchat the emphasis is rightly laid on the family for it is the soldier's wife with a brood of children who is having the hardest time today Even with schools and day-nurseries it is difficult for her to get really remunerative work, and yet give her children the care and attention they need But the wife without children can supplement her allowance with a well-paid job—indeed the Government is anxious that she shall volunteer to help build a spitfire or a tank Or she may join one of the women's services where she not only gets her board lodging, and pay but also receives an allowance, contributed jointly by her husband and the Government With plenty of work for everyone and not enough money to give as much as we would like to the soldier s children should we not think again about the distribution of our pennies and consider making motherhood and not marriage the qualification for an allowance ?

QUESTION TIME

Medical Advisory Committees

In answer to a question from Sir ERNEST GRAHAM-LITTLE the Minister of Health said that none of the members of his medical advisory committees receives remuneration for their services Their membership is as follows —

Central Medical War Committee—H S Souttar F R C S (chairman) H Guy Dain M B J W Bone M B H W Pooler, M B Colonel A H Proctor, M D Prof P M F Picken M B W E Thomas L R.C P E E A Gregg L R C P I D G Greenfield F P C S , P Macdonald M.D J C Matthews M D Prof A H Burgess F R C S J A Brown M D , G E Elkington F R C S F W Grant, L R.C P E F Gray, M B J M Johnstone, M B , Sir Kaye Le Fleming M D S A Winstanley M B , Charles Newman, M D , Sir Charles Wilson P R.C P Sir Girling Ball F R C S Sir Alfred Webb-Johnson P R.C S Prof W Fletcher Shaw, P P C O G T G H Shore M D Russell J Reynolds M B , D Embleton M B J D M Cardell F R C S A A W Petrie M D , C B Heald M D Prof Harry Platt, M S G Lilico M B Janet Aitken M D , Sir Francis Fremantle, M D Z Mennell M B P N Panton M B , J Alison Glover M D Sir Hubert Bond, M D R W. C M.W C and Home Guard

Replying to a question Mr BROWN said that to avoid undue interference with the medical organisation of the locality, Army Council instructions provide that no medical practitioner is to be enrolled in the Home Guard unless previous permission has been given by the local medical war committee It is open to any practitioner aggrieved by the Committee s decision to communicate with the C M W C under whose general directions the local committees act If he is dissatisfied with the conclusion of the central committee and wishes to make representations to me I shall of course be prepared to consider them. There is no representative of the Home Guard as such in the membership of the central committee but an observer attends on behalf of the War Office

Medical Man-power

An interim report has been received from the Shakespeare Committee and action is being taken on the recommendations These include suggestions for the establishment of regional committees to promote the maximum coöperation between civil and service medical establishments, the continued recruitment for the time being of medical officers for the Forces at the rate at which they are now being recruited, the compilation of particulars of bed accommodation and staffing for all civil hospitals and measures to secure greater mobility of resident medical staffs as between one hospital and another (Mr BROWN replying to Sir FRANCIS FREMANTLE.)

Alien Doctors

Under a recent order an alien doctor who fulfils the other necessary conditions may be placed temporarily on the Medical Register if he is to be employed as an assistant to a British doctor in private practice The employment is in each case subject to the approval of the Home Secretary (Mr BROWN replying to Miss E. RATHBONE.)

Milk in Schools

In answer to a question addressed to the President of the Board of Education, Mr J C EDE stated that in May, 1941, had forgotten all about him till the other week when one of these minor food crises which are continually cropping up reminded me of him I hesitated a long time Could I really have the brass neck to call on him, inquire after his health and gradually lead up to the major question of whether he could help me? In the end the domestic shortage of biscuits won the day—I took the plunge and the next time I was in his neighbourhood boldly entered his shop I am sure he saw through me at once but he played his part like a gentleman, and a weekly call now seems part of the routine of a visit to town The result is that I am never so popular at home as on the day of my London visit, whence I now return with a medley of biscuits, jellies, tinned fruit blancmanges or lime juice—all those little extras utterly unessential to life but so delectable to the palate of a child Actually my youngsters do not do too badly, as I usually manage to produce a weekly ration of chocolate from the enterprising steward of one of my hospitals who keeps a secret, if small, store of confectionery

Another minor shortage which is threatening to modify our social habits is the scarcity of sherry I must confess to a certain disappointment when twice within a week I was invited out to dinner and both times had to sit down to a completely teetotal meal, and when this was followed by an invitation to coffee, because "sherry is so difficult to get these days," I felt that life really was becoming rather hard But when I tackled my own wine merchant he said he could let any of his customers have half a dozen bottles of sherry a week, and if any *Lancet* reader has the price of half a dozen I will reveal his name I shall expect a non-teetotal dinner in return

* * *

There have been a lot of letters in the *Lancet* lately about the treatment of venereal diseases in the Forces It is all very well the military saying that opportunities are given for treatment, when necessary even by doctors who are not in uniform in establishments administered by civilian authorities I know that most commanding officers do their best for their men, but there is still the idea that a man with v d is a defaulter There is no point in arguing about this, it is certain that he is also sick and that to deprive a man with gonorrhœa of his treatment because his unit is going on manœuvres is not only unfair to the man but military shortsightedness, for it may lead to his permanent invalidism and loss from his unit If the military really think (which I don't) that punishment has a prophylactic effect let it be given when he is cured and let his cure be expedited in every way

There is another side to the question which seems to be almost completely neglected There are concentrations of men in isolated rural districts which have only a very rudimentary public-health service The soldiers get their treatment (and perhaps their punishment) without difficulty In the case of their contacts the situation is reversed The incidence of untreated female v d in certain rural districts is truly horrifying It may be said that medical men as scientists have no business to be horrified, but what horrifies me is the attitude of local health authorities which refuse to recognise the very existence of the problem

* * *

My wife has remarked that it's all very well my being high falutin' but what about infant's food Admittedly we have an allergic daughter (Freud never explained why doctor's daughters are allergic) but the difficulty today in obtaining any artificial baby-food seems disproportionate No doubt brands of artificial food are more numerous than the physiological needs of infants demand, but something should be done to standardise the position There are times when we cannot buy any brand of cereal food in a market town of 12 000 inhabitants for a year-old child Surely the manufacturers could agree among themselves and produce several standard products suiting various age-groups and requirements and thus remove at one blow present distribution difficulties and the artificial complexity of an advertisement-controlled market While we are on this subject, why should not oranges be only purchasable on production of an infant's ration card? That would do more good to our war effort than using them as a diluent for gin in an A T S subaltern's cocktail at a Thames-side inn Yes, I can hear you asking what I was doing there The answer is that I would'nt drink a Bronx if you stood me one I like my alcohol recognisable

---

[1] See *Lancet* Sept 27 1941 p 373

There is no scarcity of articles on boxing , the value f most of these articles however is limited At the resent stage of development of this new branch of edicine efforts must be concentrated on presenting ell-studied case-histories The " critical " and " systeatic ' publications of other more established branches f medicine are simply not available Case-histories are n fact the medical equivalent of the measurement of uantities in the pure sciences

Some medical writers (Winterstein 1937/38 Knoll 938), more especially those who are extensively quoted n the lay press, abound in general statements about the edical implications of boxing but fail altogether to atisfy the above demand Winterstein, for example, nstead of presenting evidence, gives highly speculative psychological interpretations of incidents in the ring On the other hand, experienced research workers like Parker, Guttmann, Bowman and Blau, Carr and Moody, and the Director-General of Health of New Zealand (Dr Watt), have presented admirable case analyses In evaluating the evidence I have laid emphasis upon this latter category Every good case description was carefully considered and if deemed advisable, included in my book I did not hesitate to describe in detail Guttmann's excellent history of a case of paralysis of the right anterior serratus muscle in a boxer, while rejecting unsupported and medically valueless statements on punch-drunkenness With regard to the latter condition, my own observations as well as a critical review of the few case-histories available in the literature showed me that we are not dealing with a clinical or pathological entity but with a multitude of conditions which still await an analytical neurological study This is in agreement with the view expressed, for the first time, by E Guttmann and myself in 1933 I therefore confined myself in my book to the presentation of original evidence never before collected, without drawing premature conclusions on its pathological significance I abstained from discussing topics of which I have no personal experience , that is why the manifold ophthalmological problems of boxing are not treated in my book

Finally, I asked myself whether the evidence at my disposal allows the drawing of definite *practical* conclusions In the past the reluctance of research workers to apply conclusive scientific evidence to practical issues has been to the disadvantage of medicine Notwithstanding that our knowledge of the medical aspect of boxing is as yet incomplete—knowledge is never complete —it is my considered opinion that the collected evidence warrants the demand that *boxing be eliminated* from all educational institutions and from the armed forces

EXCLUSION OF NEUROTICS FROM THE FORCES

SIR —May I endorse Dr Minski's letter of Sept 27 ? It is by now becoming obvious to those of us who work in the field of psychiatry that the psychotic and psychoneurotic are unsuitable persons for active service in the Forces I believe this view to be shared by combatant officers I admit that such a generalisation is capable of modification in individual cases Dr Minski's suggestion that a psychiatric examination should be available at the time of medical examination appears entirely reasonab[illegible] nd not too difficult of arrangement That medical [illegible]ination boards should have all specialist services at their call is surely desirable

To the story of the epileptic who had enlisted five times I would add that within an hour of reading Dr Minski's letter I heard that a youth whom I had examined in 1939 when he was a schoolboy, and whom I considered to be a schizophrenic with a bad prognosis, had just been " discharged from the Army "

Taunton R SESSIONS HODGE

HOME GUARD PROBLEMS

SIR,—Mr Abel seems to have been singularly unfortunate in his relations with the Red Cross In my case, far from proving " so exsanguinated by red tape as to be almost invisible on its white background," the Red Cross has proved an exceptionally full-blooded friend in need to the Home Guard Not only has the Red Cross Society accepted the responsibility of completing the equipment of casualty collection posts to a rather more exacting standard than that laid down by Mr Abel but they have also relieved at least one Home Guard medical officer of a great amount of the office work involved in the setting up of these posts Whilst a thinly populated rural district does not call for the establishment of a C C P at intervals of not more than one mile it does demand a sufficiently high standard of equipment and staff to enable casualties to be cared for at posts over a period of possibly many days, and it is solely due to the energy and freedom from red tape complexes shown by the British Red Cross Society that this has been accomplished in my area

H MARCUS BIRD.

SIR,—Your correspondents agree that in case of invasion casualties are most likely to occur in isolated country districts where there are few facilities for coping with them, and that Home Guard M O s should equip casualty collecting posts wherever they may be needed May I endorse Dr Sinclair-Loutit's suggestion that they will find competent assistants in the local district nurses —women who by training and experience are equipped to cope with any emergency, to assume responsibility in the absence of a doctor, and to improvise when orthodox material and methods are not available ? The district nurse knows the neighbourhood, the buildings the people She can advise on the choice of a post, and organise her own local team of helpers Most important of all, she can be left, under instructions, to deal with the casualties while the sorely pressed M O goes to other places more urgently needing him The doctor could have no more reliable deputy

J ELISE GORDON

London, S.E 1 Editor, *Nursing Mirror*

CORROSIVE STRICTURE OF THE STOMACH

SIR,—The interesting account given by Mr C A R Schulenburg in your issue of Sept 27 reminds me that I have been remiss in not reporting a case of this nature which occurred at the Royal Free Hospital in 1938.

Man aged 32 Admitted under Dr Lee Lander June 3, 1938, having swallowed " considerable quantity ' of strong HCl Usual remedies applied at once June 6, began to vomit By the 16th, when he had a hæmatemesis, vomited practically everything he took Hæmoglobin, 54% five days after hæmatemesis, rose slowly to 60% on Campolon and ferrous salts

July 8 test meal showed complete achlorhydria Blood present on this and other occasions June 28 barium meal revealed normal œsophagus but advanced atresia of pyloric end of stomach, little evidence of barium passing through July 8 barium meal showed more gastric dilatation, no barium was passed through in 24 hr July 15 . I carried out a partial gastrectomy for almost complete stenosis extending from pyloric ring proximally for nearly 2 in Mucosa of this portion of the stomach completely replaced by vascular granulation tissue, proximal to which was abrupt transition from inflamed part to normal gastric wall

Aug 4 patient left hospital in excellent condition having gained 5 lb following operation

As in Mr Schulenburg's case the onset of stenosis was rapid, indeed it appears to have been nearly complete at the time of the first barium meal I have not had the time to search the literature but as partial gastrectomy is not mentioned in Mr Schulenburg s article presumably it has not been adopted before, yet it appears to me to have advantages over mere short-circuiting operation since it extirpates a segment of the stomach that is extensively damaged and the site of changes which may well develop into chronic ulcer of a peptic or even malignant nature In my own case there were no special technical difficulties to overcome and the light percaine spinal anæsthetic with which I am accustomed to work was well borne

Harley Street, W 1 CECIL A JOLL

the number of public elementary school children in England and Wales receiving milk under the scheme was 2,700,000 compared with approximately 2,100,000 in March, 1940 Including schools other than public elementary schools it is estimated that in May, 1941, nearly 3,000,000 children were taking milk in school under the scheme

Milk for the R A F and Others

Replying to Flight Lieut Ralph Etherton, who asked whether it was proposed to modify the present nil issue of fresh milk to R A.F units, Major Lloyd George said that the present demand for milk is considerably greater than the estimated production during the winter months and to ensure adequate supplies for mothers, infants, children and invalids, a scheme of controlled distribution will be introduced on Oct 12 on the lines indicated in his reply of Aug 6 Adult consumers will receive part of their supplies in the form of condensed milk which will be available in much greater quantities than last winter, and it has been arranged that, save in special circumstances, the supply of milk to the Services shall be in this form

Medical Prisoners of War

Mr D Sandys, financial secretary to the War Office, stated that some 500 medical personnel and chaplains are entitled to repatriation under the International Convention of 1929

Increase in Tuberculosis

Replying to Dr E Summerskill Mr Brown said that he had arranged for a special inquiry to be made, with the assistance of the Medical Research Council, into the causes of the war time increase in tuberculosis The latest information available shows that on June 30 there were 1763 persons in England and Wales who had been on local authority waiting lists for institutional treatment for upwards of 10 days Arrangements were being made to release some E M S beds, but it was not merely a question of beds, but of nurses

Answering a further question, from Sir E Graham Little, Mr Brown gave the following table of female death rates (per million) from tuberculosis in England and Wales

—	Respiratory		Other forms	
	Ages 15–20	Ages 20–25	Ages 15–20	Ages 20–25
1936	670	1039	129	97
1937	652	1029	130	116
1938	605	931	132	93
1939	601	955	137	90
1940*	692	1103	146	132

* Provisional, based on the 1939 population

Medical Aid for China

Mr A Eden announced that the Government have agreed to make a grant in aid of £50,000 to the British Fund for the Relief of Distress in China

Annual Reports

Replying to Sir F Fremantle, the Minister of Health stated that the regular series of reports of his department and of his chief medical officer will be suspended till after the war, but a summarised report will probably be ready within the next two months The President of the Board of Education proposes to defer the annual reports of his chief medical officer until after the war The Minister of Labour hopes to issue the report of the chief inspector of factories for 1940 within the next three or four weeks

---

Hospital Survey in Bristol and District —The new Bristol Hospitals Commission is sitting at the Council House, Bristol, Oct 6–9 to initiate a survey of hospitals, voluntary and municipal, and of teaching services in the area with a view to meeting current needs and the expansion and reconstruction desirable after the war is over The Lord Mayor has invited local contributory schemes to submit observations to help solve the financial problem of the voluntary hospitals The commission consists of Sir Farquhar Buzzard, Sir George Martin, Prof G E Gask, Dr M T Morgan, Dr John Buchan, Dr J P Candler, Dr A Q Wells, Alderman W Hyde and Mr S Clayton Fryers

Letters to the Editor

MEDICAL ASPECTS OF BOXING

Sir,—In an excellent book J G Crowther (194 maintains that one of the outstanding scientists of t last century was Sir Humphry Davy Davy was t first scholar who "sold science to the industrialist who applied to a practical purpose a mass of exp information, making available to the people the fru of a hitherto exclusively academic field of learning T present state of physical education reminds me of th of British science in the time of Davy, Faraday a Joule Physical education is one of the younge children of science, unknown in its scope not only the general public but to the majority of educat people There are few whose concept of its medical implications enables them to apply our present knowledge Physical education and sport are today still based on empiricism, not on scientific information, and many years must elapse before a rational attitude determines our policy

Of all important branches of physical education, boxing is the only one in which injuries are not accidental events but form the essential aim of the sport Every boxer tries to disable his adversary by hurting him, preferably through inflicting a head injury of such an intensity as to produce a state of unconsciousness The fact that the various ring injuries have been dignified by popular terms such as "knock-out," "groggy," "punchdrunk" and others can, of course, not obscure the true picture This was the essential point I endeavoured to bring out in a book which you have critically reviewed (*Lancet*, June 14, pp 756, 759) without even mentioning my main argument In my book I laid stress upon the unavoidability of head injuries being produced in amateur as well as professional boxing fights conducted under "regulation conditions" Ample evidence was presented to the effect that blows to the head, even if they do not lead to the immediate collapse of the fighter, very commonly are followed by serious after-effects, that the chin knock-out is a concussion of the brain notwithstanding the fact that it is caused by a specific traumatic mechanism and that its clinical sequelæ distinguish it in some respects from other forms of concussion

Surely, Sir, all this is "incontrovertible medical evidence" which, incidentally, has been accepted by leading neurologists, among them Fulton and Hassin, who have expressed their agreement with my views At a recent Air Force boxing tournament five bouts ended through knock-outs Three of the unfortunate victims hit the floor with their occiputs while falling to the ground in an unconscious state I am at a loss to understand how "repeated neuropsychiatric examinations" should be able to make such routine injuries impossible I challenge any flight surgeon who wishes to tell me that the above mentioned Air Force boxers would not be severely handicapped in the course of their duties during the days following the knock-outs No logically thinking physician can fail to see the difference between athletic accidents in general which are accepted as unavoidable accompaniments of every manly sport, and the deliberate infliction in the ring of brain injuries many implications of which we have only recently learned to understand Against this danger of head injuries other boxing injuries play a much less significant rôle, as my survey has revealed for the first time The conclusion at which I arrived was clearly stated thus "The dangers of boxing can only be eliminated by the total abolition of this sport" More especially, I felt it my duty to press for the immediate removal of boxing from the recreational programme of the armed forces

The evidence on which I base my thesis that boxing must go divides itself into several categories Primarily I rely on personal experiences and observations as well as the results of experimental and clinical investigation over twelve years Taking a rather unorthodox view with regard to the extent to which medical information should be applied to practical issues, I have not hesitated to make use of descriptions given by boxers and other non-medical persons While the quality of such contributions, naturally, varies within wide limits, I agree with Brend (1938) that whenever we deal with a social *eaths* —In 126 great towns there were no deaths n measles, 3 (1) from enteric fever, 1 (0) from scarlet r 15 (1) from whooping-cough, 28 (1) from diphtheria. 2) from diarrhœa and enteritis under 2 years and) from influenza The figures in parentheses are those London itself

eater London, Watford and Blackburn each reported a death n enteric fever There were 4 fatal cases of diphtheria and 3 of oping-cough at Liverpool

number of stillbirths notified during the week was (corresponding to a rate of 32 per thousand total ths), including 14 in London

Medical News

yal College of Surgeons of England

The following demonstrations, which are open to advanced dents and medical practitioners, will be delivered at the lege in Lincoln s Inn Fields, London W C 2, during tober at 2 30 P M. Oct 13 Dr A. J E Cave, constitution the skull, 14 Mr L E C Norbury, benign neoplasms of rectum, 15 Dr Cave, vascular arrangements of the ad and neck, 16 Mr Norbury, malignant neoplasms of e rectum. 17 Dr Cave, lymphatics of the head and ck, 20 Dr Cave, surgical anatomy of the nasal fossa, Mr R Davies Colley, diseases of the testicle, 22 Dr ve, surgical anatomy of the mouth and jaws, 23 Mr E Shattock, tumours of the kidneys; 24 Dr Cave, rgical anatomy of the pharynx and larynx, 27 Dr Cave, rgical anatomy of the liver and bile ducts, 28 Mr avies Colley, tumours of the intestines, 29 Dr Cave, surgical atomy of the kidney and ureter, 30 Mr Shattock, tumours bone, and 31 Dr Cave, surgical anatomy of certain nerves

niversity of Birmingham

Dr Stanley Barnes has retired from the office of dean of the edical faculty which he has held for ten years In accepting s resignation the council passed the following resolution

> For nearly 40 years in addition to being actively associated with e local hospitals, Dr Barnes held a pre eminent position as a nsultant He sacrificed a lucrative practice to enable him to sist with the planning and building of the Hospitals Centre and the ew buildings of the Medical School at Edgbaston He always set r himself and others a high ideal of learning and scholarship and aff and students for many years have owed much to him for the bility and unflagging zeal he has showed in promoting the interests f the Faculty with which he has been so closely associated He as given liberally to the building funds of the Medical School nd the excellence of the building and equipment, generally cknowledged to be unsurpassed elsewhere, reflect in many directions e effect of his constant supervisory care

Prof Leonard Parsons, who has been deputy to Dr Barnes r some years, has now been appointed dean Dr Parsons ill continue his work as physician to the United and the hildren's Hospital and regional officer for the Midlands to the inistry of Health

Prof Lancelot Hogben, F R S, who has held the chair of atural history in the University of Aberdeen since 1937, as been appointed to the chair of zoology at Birmingham in ccession to Prof H. Munro Fox

S M M G Salaries

The Chartered Society of Massage and Medical Gymnastics as recommended the following scale of salaries It has een approved by the Ministry of Health for members of M S hospitals qualified in massage, medical gymnastics, edical electricity, and light therapy

	Resident	Non-Resident
hartered masseuse or masseur	£85–£10–£115*	£210–£10–£240*
Where only one masseuse or masseur is employed	£115–£10–£145	£240–£10–£270
harge masseuse or masseur—		
Where two masseuses or masseurs are employed	£145–£15–£175	£270–£15–£300
uperintendent masseuse or masseur—		
Where three to ten masseuses or masseurs are employed	£175–£15–£205	£300–£15–£330
Where more than ten masseuses or masseurs are employed	£205–£15–£235	£330–£15–£360
ermanent part time appointments (21 hours work per week)		£130 per annum
essions of 3 hours or less		*10s 6d*

After 5 years service with same authority, and if recommended 3 further annual increments of £10

Members required to hold the additional certificate in ydrotherapy should be allowed a further £5 per annum, and hose required to hold qualifications of other organisations uch as S R N M S R, a further £20 per annum Length of ervice and experience should be taken into consideration and where no superannuation scheme is in operation the salaries given above should be increased. Where cost of living additions are granted the special bonuses should be in addition to the minimum figures given on this scale

Naval Honours

The R N V R officers' decoration has been awarded to Surgeon Commander George McCoull, M.D Durh., and to Acting Surgeon Commander G F S Parker, M.R.C S

Medical Casualty

Surgeon Lieut -Commander C D D de Labilliere M R C S R N, has been reported missing presumed killed, after the sinking of H.M.S *Fiji* off Crete in May

Medical Society of London

A meeting of this society will be held at 11, Chandos Street, London, W 1, on Monday, Oct 13, at 4 P M. After the presentation of the Fothergillian medal there will be a pathological meeting

Shaftesbury Military Hospital Medical Society

A meeting of this society will take place at the hospital on Tuesday, Oct 14, at 3 P M., when Colonel J M Weddell consulting surgeon to the Army, will survey the present position of surgery in the army

Royal Medical Society of Edinburgh

Sir William Wheeler will open the new session of this society on Friday, Oct 17, at 8 P M when he will give an address on what society has gained by the progress of surgery During the session addresses will be given by Colonel F A E Crew, Prof G B Fleming, Prof A. T Jurasz, Dr J Trueta and Prof Samson Wright The annual dinner will not be held this year

Births, Marriages and Deaths

BIRTHS

ALCOCK.—On Oct 1 at Oxford the wife of Squadron Leader N S Alcock M.R.C P —a daughter

BURDEN —On Sept 29 at Alverstoke, Hants, the wife of Surgeon Commander A. J Burden, M.B, R.N —a daughter

CAMPBELL.—On Oct 1 at Cambridge, the wife of Captain E C Campbell, M R C S, R.A.M.C —a daughter

HENDERSON —On Oct 1, at Pitlochry, the wife of Captain Walter Henderson M D R.A.M C —a daughter

HIGHAM —On Sept 29, at Didsbury Manchester, the wife of Major A R C Higham, F R.C S, R.A.M C —a son

INGLIS —On Sept 28 in Glasgow, the wife of Dr W Elder Inglis, a son

MARRIAGES

BOWEN-JONES—CORBETT —On Sept 14 at Liverpool John Anthony Bowen Jones M B surgeon lieutenant, R.N V R to Eileen Anne Corbett

MANSON—MILLER.—On Oct 1 at Streatham, London Malcolm Manson M.D to Margaret Miller M B

MOLE—BROOK FOX.—On Oct. 2 at Halberton Richard H Burnell Mole, M.R C S, to Catherine Rosemary Brook Fox

DEATHS

CROSSE —On Oct 5, at Brundall, Herbert William Crosse M D Edin, barrister at-law

KERR —On Oct. 5 at Edinburgh, James Kerr, M A, M.D Camb, D P H sometime school medical officer of London

KERR RUSSELL.—On Oct 5, William Kerr Russell, M.D Durh, Ross-on Wye late of Harley Street W 1

WOOD —On Sept. 27 Leonard Wood, M.R.C S colonel late R.A.M C of Westbury, Wilts aged 67

YOUNG —On Sept. 26 at Leeds, George Young, M.B Glasg, late of Cockermouth Cumberland

Appointments

BARKER KATHLEEN M R C S R.M.O at Ilford maternity home

BRASS J C M R.C S R S O at Poplar Hospital

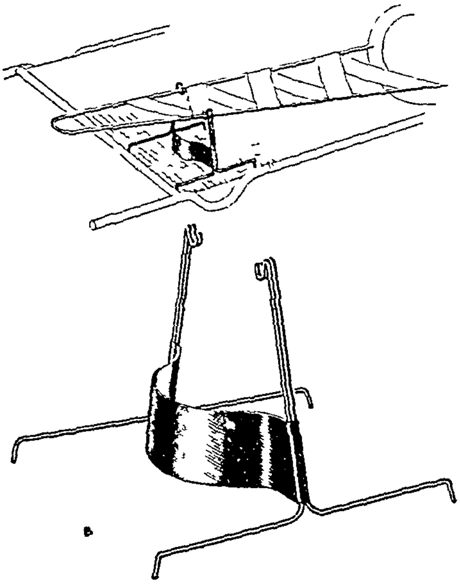
STRETCHER SUPPORT FOR THOMAS SPLINT

SIR,—Mr W G Morden of the Beckenham civil defence service, has designed the simple piece of apparatus here illustrated for the use of stretcher parties transporting a patient wearing a Thomas splint The cost of material is negligible and the fitting can be made by any handy man within an hour The fitment is intended for use with the standard pattern A R P wire stretcher It eliminates the need for the regulation suspension bar and requires no delicate adjustment Made from ¼ in iron rod and a piece of sheet tin it can be instantly adjusted to give support at any point along the length of the splint by a simple flexion movement It measures 10 in by 10 in by 9 in high



Beckenham, Kent T PHILIPS COLE

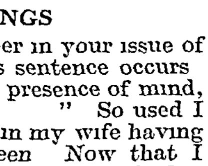
WASP AND BEE STINGS

SIR,—In Dr Dyke's interesting paper in your issue of Sept 13, in the report of case 2, this sentence occurs " One of the girls, with commendable presence of mind, put ammonia on the site of the sting " So used I to do, and the last time this resulted in my wife having the worst wasp-sting I have ever seen Now that I know better I put vinegar on and have never had a moment's anxiety since adopting this method, even with what I should once have considered serious stings of the lips, tongue or fauces As far as I know the necessity for using dilute acids for wasp-stings and dilute alkalis for bee-stings was first pointed out by Mr Edward R Speyer in a letter to the *Times* of Aug 20, 1919, which was commented on in the *Lancet* for Sept 6, 1919 (p 445) An interesting correspondence on this subject ran in the *Times* from Aug 20 to Sept 9, 1938

Guildford OSMOND H BROWN

INGROWING TOENAIL

SIR,—Mr Nuttall's article of July 26 and Mr Bonnin's letter the following week renewed an interest in ingrowing toenail which I have long felt With Mr Bonnin I consider that Mr Nuttall's summary of the ætiology—" tight shoes "—does not cover all the cases Like Mr Bonnin I have noticed a decidedly familial tendency and cannot believe this is due to tight shoes Choyce's " System of Surgery " states that it generally occurs in young adults, in men more often than women My own experience accords with this view both as regards the age and sex of the majority of these patients If the ætiology is solely tight shoes would it not be reasonable to expect that the cases would be much more numerous among women and that many cases would be found in later life ? Both the occurrence in several members of one family, parents and siblings, and the shape of the nail lead me to believe that a certain proportion of cases are congenital defects or rather variations from what we consider normal It does not seem accurate to say that " there is no ingrowth of the toenail" in this group of cases Although many ingrowing toenails are flat and cannot be said to be ingrown a certain proportion are definitely curved in the horizontal plane and this variation seems to run in families The free border of the nail, as viewed from beyond the tip of the toe is not merely slightly curved but forms almost half an ellipse as shown in the drawing The abnormality commonly occurs in children This curvature of the nail must produce an exceptionally deep lateral nail fold which would surely not increase the pressure on the skin f the edge of the nail if the shoes are tight but rather decrease it, since now the nail border is parallel to the lateral nail fold and the lateral pressure would appear to be less likely to cause ulceration by pressure on the nail edge A case I have recently seen caused me to query the effect of tight shoes A lad of twenty had been in bed in this hospital suffering from rheumatic carditis, and of course had worn no shoes of any kind, immediately before this illness he had been in the R A F for fifteen months After fourteen months in bed he developed " ingrowing toenail " with severe sepsis on both sides of both big toenails He had deep creases on either side of the nails which were exceptionally curved, and he denies ever wearing tight shoes, we know that this is true for at least 2½ years before his toes began to cause trouble Can medical officers with wide colonial or other native experience tell us whether the condition we call ingrowing toenail is found in races who do not wear shoes ?



Horton Emergency Hospital E J RADLEY SMITH

Obituary

CHARLES LEONARD DIGBY ROBERTS

M B EDIN, D T M & H

Dr Charles Roberts, who remained in Guernsey to look after the civilian sick during the German occupation, died in St Peter Port on April 12 soon after undergoing a major operation He was born in Exmouth in 1882 and graduated from Edinburgh University in 1908 He came to Bart's to study for the English fellowship, and passed the primary examination But he became interested in tropical medicine and went out to India, where he spent the greater part of his professional life For some years he was medical officer at the Charteris Hospital in Kalimpong, a remote outpost which was the railhead for many Mount Everest expeditions At the outbreak of the last war he joined the Indian Medical Service, and saw service in the Waziristan and Persian Gulf campaigns After the war he practised for a short time in Darjeeling before he went to Assam, where he was medical officer to the Mariana Tea Association for many years When he retired from India he went to practise in Guernsey, where he had hoped to enjoy a well earned rest

Roberts's chief hobby was the study of natural history, and in India he amassed a fine collection of butterflies Some of his specimens were new discoveries and are preserved in the Natural History Museums in South Kensington and Bombay His knowledge of the flora of the Channel Isles delighted those who accompanied him on his energetic walks along the cliffs and country lanes

Dr Roberts is survived by his wife, daughter and three sons The sympathy of all will go out to Mrs Roberts in her lonely exile

Infectious Disease in England and Wales

WEEK ENDED SEPT 27

Notifications —The following cases of infectious disease were notified during the week smallpox 0, scarlet fever, 1258, whooping-cough, 2247, diphtheria, 1066, paratyphoid, 100, typhoid, 32, measles (excluding rubella), 745, pneumonia (primary or influenzal), 185, puerperal pyrexia, 123, cerebrospinal fever, 94, poliomyelitis, 38, polio-encephalitis, 3, encephalitis lethargica, 6, dysentery, 89, ophthalmia neonatorum, 98 No case of cholera, plague or typhus fever was notified during the week

The number of civilian and service sick in the Infectious Hospital of the London County Council on Sept 24 was 1246, including scarlet fever 137 diphtheria 272 measles 23 whooping cough 534, enteritis 24 chicken pox 29 erysipelas 24 mumps 7 poliomyelitis 3, dysentery 13 cerebrospinal fever, 15, puerperal sepsis 9, enteric fevers 42 malaria 1 polio encephalitis, 2, other diseases (non infectious) 35, not yet diagnosed, 76

HÆMOGLOBIN METABOLISM

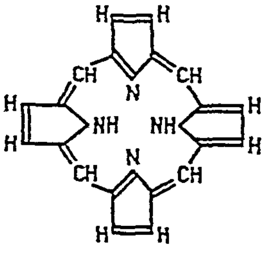
M C G Israëls MD MSC MANC, MRCP
ASSISTANT DIRECTOR OF THE DEPARTMENT OF CLINICAL INVESTIGATION AND RESEARCH, UNIVERSITY AND ROYAL INFIRMARY, MANCHESTER

When Hans Fischer began the study of the pigments excreted in the rare condition of congenital porphyria. it could hardly have been foreseen that the extension of this work would lead to a more thorough understanding of the metabolism of respiratory pigments in general, including hæmoglobin Such investigations are difficult, and although Fischer and his co-workers synthesised hæmin in 1929 much further chemical groundwork has been needed before the results could be applied to the clinical problems of blood-diseases

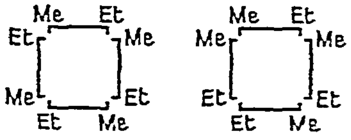
Hæmoglobin is formed by linking together a protein—globin—with an iron-containing pigment "protohæm" This protohæm is a combination of ferrous iron with a substance "protoporphyrin" which is closely allied to the pigments excreted in congenital porphyria. Fischer and his school have shown that all the naturally occurring porphyrins are variations on one theme—the "porphin" nucleus which is made up of four pyrrol rings joined by methene bridges (formula A) When the eight H atoms on the bases of the pyrrol rings are replaced by four methyl (Me) and four ethyl (Et) groups an artificial compound called "ætioporphyrin" is obtained There are four possible isomeric ætioporphyrins, but the naturally occurring porphyrins all correspond to series I (formula B) or series III (formula C) There is no simple chemical way whereby series I compounds can derive from series III or vice versa, breakdown of the porphin nucleus and resynthesis would be needed and this is thought to be a very unlikely occurrence The different porphyrins have different side-chains replacing the eight H atoms in porphin Thus protoporphyrin has four—one CH_3, two $CH=CH_2$, and two CH_2-CH_2-COOH groups Coproporphyrin, the normal excretion form has four CH_3 and four CH_2-CH_2-COOH groups, uroporphyrin, with four CH_2-COOH and four CH_2-CH_2-COOH groups appears only in the porphyrias Now the protoporphyrin of hæmoglobin belongs to series III, and Watson[1] showed that the free protoporphyrin in reticulocytes is also series III. Normal people excrete small amounts of coproporphyrin, about two-thirds in the fæces and a third in the urine: but all the fæcal and at least half the urinary coproporphyrin is series I and cannot therefore have been derived from the breakdown of hæmoglobin Patients with hæmolytic anæmia known to be destroying large numbers of erythrocytes excrete relatively large quantities of coproporphyrin, but surprisingly this again is all series I This unexpected finding that the excreted porphyrin is a different isomer and is therefore not derivable from the hæmoglobin porphyrin was called by Fischer the "dualism of the porphyrins" and has to be taken into account in any study of porphyrin excretion designed to throw light on hæmoglobin metabolism It is not sufficient to know how much porphyrin is excreted—we must know to which series it belongs and indeed Watson thinks it more important to know which than how much Unfortunately the determination of the isomeric type is far from simple, it demands[2] the separation of the porphyrins, the preparation of their methyl esters and the determination of melting-points; and since the amounts excreted daily are measured in microgrammes, or only occasionally in milligrammes, skilled chemical technique is essential For these reasons little data is at present available, but what there is is important

In pernicious anæmia[3] there is greatly increased excretion of coproporphyrin I When specific liver treatment is given the porphyrin excretion continues raised until after the reticulocyte peak is passed, then it slowly falls to normal Coproporphyrin I is also excreted in large amounts in hæmolytic anæmia and in the period of blood-regeneration after hæmorrhage[2] In aplastic anæmia[4] on the other hand, from a fifth to a tenth of the excreted coproporphyrin is series III, and coproporphyrin III has also been found in poisoning by lead,[2] sulphanilamide[5] and other substances Hence the excretion of coproporphyrin I seems to be linked with unusual erythropoietic activity, including the megaloblastic erythropoiesis of pernicious anæmia, but excretion of coproporphyrin III seems linked with depressed erythropoiesis In the first group there is always evidence of excessive destruction of red cells, but as already pointed out the coproporphyrin I cannot have come from the red cells Is the coproporphyrin III of the second group derived from hæmoglobin? Apparently not. Lemberg's[6] studies of hæmoglobin breakdown have revealed that porphyrins are not formed; the porphin nucleus opens while still attached to globin and iron and thereafter is converted into biliverdin and bilirubin; the excretion forms of bilirubin urobilin and urobilinogen, are therefore used as indicators of hæmoglobin destruction.

Ingenious explanations of these contradictions have been suggested by Rimington[7] Dobriner and Rhoads,[2] and Turner[8] They all suppose that from a pyrrolic precursor porphyrins of series I and III are formed simultaneously, normally much more III than I, but if the production of III is increased I is increased proportionately. The series III porphyrin is protoporphyrin and is used in the formation of hæmoglobin, but the series I porphyrin is apparently useless—it is converted into coproporphyrin and excreted Hence if there is unusually rapid formation of red cells more porphyrin III is needed for hæmoglobin and a correspondingly increased amount of porphyrin I is formed and excreted But in aplastic and toxic anæmias, owing either to the absence of erythroblasts or to toxic interference with hæmoglobin synthesis, the porphyrin III still being formed is unused and is excreted as coproporphyrin III The changes in congenital and acute porphyrias are attributed to disturbance of this orderly synthesis There is no real evidence in support of this theory but it fits the facts partly at least Rimington and Hemmings[9] have shown that toxic drugs like sulphanilamide which cause methæmoglobin formation also cause increased porphyrin excretion and this is coproporphyrin III Hence they suggest that this may represent an alternative method of hæmoglobin breakdown, but occurring only when methæmoglobin is a phase in the cycle



Formula A



Formulæ B and C

Clearly there is still room for much more evidence before confident interpretations are possible but the type of problem these results can be applied to is illustrated by Vaughan and Saifi's[10] investigation into the cause of anæmia in chronic infection The porphyrins excreted by their patients were estimated by Rimington who reported a rise in the excretion of both series I and III. Since there was no evidence of increased hæmoglobin breakdown it was concluded that a disturbance of hæmoglobin synthesis was responsible In a previous paper,[11] by correlating cytological examination of the bone-marrow with clinical findings I was able to divide erythropoietic disturbances into broad groups Further subdivision of these groups may well come from biochemical studies of hæmoglobin metabolism which can detect the conditions in which hæmoglobin is insufficiently available for normal marrow cells The difficulty of the biochemical methods involved still stands in the way of really systematic investigation of the anæmias from this point of view As Watson has said what we need is a differential method permitting estimation of the amount of each isomer present without recourse to actual isolation. Until this happy day comes we must proceed, where we can, with the determination of the porphyrin isomers appearing in the various anæmias so

Notes, Comments and Abstracts

HOME GUARD MEDICAL ARRANGEMENTS

Brigadier E M COWELL F R C S

SOME notes on Home Guard medical arrangements from the Corps point of view, prepared for the course recently held at St John's College Cambridge, may perhaps be found useful for a wider circle

Regimental Medical Officer —The Home Guard medical officers appointment is not a sinecure He has an immense amount of work to do in the next few weeks Instruction of the battalion, company and platoon officers in field hygiene sanitation and first-aid is his first task Secondly, he must train his medical orderlies and regimental stretcher-bearers, the establishment of which is authorised He must see that he has the equipment to which he is entitled and that it is tactically distributed Company and platoon aid posts may possibly be required in addition to the aid posts and points of the Civil Defence Services

Administration and Organisation —In each zone the appointment of a medical adviser is now officially recognised In many areas it is agreed that this officer should be a member of the public health service, either a senior M O H who has made the civil medical arrangements himself, or his deputy or junior who is familiar with the existing arrangements By coopting the Civil Defence into the Home Guard many difficulties will be overcome These zone advisers must work in close contact with the A D M S area, who will do everything to help This officer is responsible to the D D M S corps for all details

Invasion Committees —An excellent plan has been initiated in East Anglia, whereby invasion committees have been established in counties, boroughs urban and rural districts with smaller committees in every parish These committees are completely representative and all invasion plans are prepared including defence, fire, food and medical Those counties and authorities who have not yet established these committees are urged to do so without delay Medical representation is essential

First Aid Posts —Keep the terminology simple The Army Medical Services recognise R A Ps , C A Ps and possibly platoon aid posts The Civil Defence Services have F A Ps which are posts or points All these posts are " collecting " , the term C C P is confusing, redundant and unnecessary A small " medical packet " containing the bare minimum of supplies should be sealed and kept in safe custody where it will be required

Conclusions —The task is urgent and consists not so much in providing and establishing new organisations as in coordinating and " buttoning up " existing arrangements which belong, for the most part, to the Civil Defence Services Provision of medical supplies is adequate , wise distribution must be carried out

THE TOOTH OF THE DANE

THE shaming partnership between civilisation and bad teeth has been freshly illustrated by Christophersen's study of 316 skulls in the National and Anatomical Museums of Denmark [1] The owners lived in the bronze and stone ages and champed away at the tough and simple diet which their essays in hunting and agriculture brought to the table—or possibly the floor They had teeth which in occlusion, alveolar shape and position resembled those of their descendants , but their molars were stout and strong, their incisors were up to their work, and the older the eater the better his teeth Caries was found in only 1 6% of 3612 permanent teeth examined, and only 15% of 274 adults had any caries at all Among children caries was present in only 7%, but was found in 2 4% of 168 milk teeth A coarse diet evidently did its work in cleansing and strengthening the teeth and in smoothing away those irregularities, fissures and cavities which favour the development of caries These rude forefathers make a fine contrast to their posterity, whether in Denmark or elsewhere Frandsen,[2] who made a study of 1200 contemporary Danish children found only 4 with completely sound dentitions dental care, it seems, falls to the lot only of childre well-to-do parents The bad state of children's t being used as an argument for establishing an o national dental service in Denmark and for arrang the systematic treatment of school children

SCIENCE AND ETHICS

THE conference last month at the Royal Instr was evidence of the tremendous urge to find the place of science in this disordered world A symp in *Nature* (Sept 6) was directed towards d the relations between science and ethics Mr C Waddington, Sc D , points out that increasing scie knowledge, notably in the fields of anthropology, s logy and psychology (if this last is yet worthy t called a science) has done much to destroy traditi ethical conceptions Science is, however, in a pos to make, and indeed cannot avoid making, a contribu to the new ethics since ethics are based upon facts of kind with which science deals So far few would w to dispute with him, but he goes on to say that beca a thing works it must be right and good Thus, ' must accept the direction of evolution as good, sim because it is good according to any realist definition that concept " But some of his critics join issue wi him here Julian Huxley reminds him that the majori of evolutionary trends are irrelevant to progressiv change and that evolutionary progress is a rare phen menom This being so it would surely be wiser to accep evolutionary changes as a series of phenomena *outsid* the scope of ethical judgment Dr Waddington is convinced that ethics cannot be avoided since they are part of the large system of compulsions and prohibitions which begins to develop in infancy Here, he thinks, lies the practical difficulty The young child may be taught that an aggressive attitude towards others must b controlled , but how and when is he to be taught that aggression includes, for example, the adoption of a unscientific attitude towards the social problem o nutrition ? We should all like to have Dr Waddington faith that the fundamental notions of the scientific ou look will seep into the minds of mothers and nurses an so be unconsciously transmitted by them to the youn He wonders whether an adequate psycho analytica study of those who have grown up in Soviet nurseri might not provide interesting evidence on this poi It has been observed, with cynicism no doubt but also with truth, that when confronted with two or m courses of action we choose the one that we least dislik but it is the moral education we receive which determin what courses of action we like or dislike It is surely o of the functions of science to equip us with the speci knowledge to enable us to think clearly and so to morally

SHILLING A NIGHT

THE thirteenth annual report of Cecil Houses (In contains Miss Eleanor Farjeon's account of an eve at one of them , to read it is to share in the pa Every evening in the Cecil Houses must be such a pa —a meeting of friends at home to exchange news, views, sympathy and jokes Not many of us can h such a chance for a shilling a night , but those who wo like to keep the party going should write to Mrs Ce Chesterton, founder and hon secretary, at 193, Gr Street, London, N W 1

Dr James Macfarlane of the Department of Health Scotland has been appointed medical liaison officer at th Scottish Office in London, and at the medical intelli section of the Ministry of Health He will maintain lia with the medical branches of the service departments a other government departments in London

ROYAL COLLEGE OF OBSTETRICIANS AND GYNÆCOLOGIST On Saturday, Oct 25, at 2 30 P M , Mr W C W Ni will deliver the fourth Blair Bell lecture His subject w be diet in pregnancy

THE LOAN OF A MICROSCOPE —The education depart of the Royal College of Nursing needs additional microsc for laboratory work in the sister tutor course Owing to present difficulty in procuring these the director would grateful to hear from anyone willing to lend or hire one more microscopes to the college for the session

HÆMOGLOBIN METABOLISM

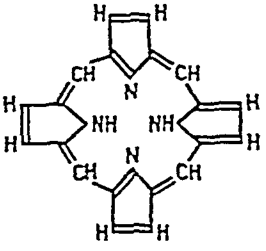
M. C. G. ISRAELS, M.D., M.SC. MANC., M.R.C.P.
ASSISTANT DIRECTOR OF THE DEPARTMENT OF CLINICAL INVESTIGATION AND RESEARCH, UNIVERSITY AND ROYAL INFIRMARY, MANCHESTER

WHEN Hans Fischer began the study of the pigments xcreted in the rare condition of congenital porphyria t could hardly have been foreseen that the extension of his work would lead to a more thorough understanding of the metabolism of respiratory pigments in general, ncluding hæmoglobin. Such investigations are difficult, and although Fischer and his co-workers synthesised hæmin in 1929 much further chemical groundwork has been needed before the results could be applied to the clinical problems of blood-diseases.

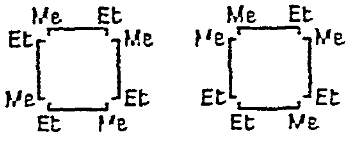
Hæmoglobin is formed by linking together a protein—globin—with an iron-containing pigment "protohæm." This protohæm is a combination of ferrous iron with a substance "protoporphyrin" which is closely allied to the pigments excreted in congenital porphyria. Fischer and his school have shown that all the naturally occurring porphyrins are variations on one theme—the "porphin" nucleus which is made up of four pyrrol rings joined by methene bridges (formula A). When the eight H atoms on the bases of the pyrrol rings are replaced by four methyl (Me) and four ethyl (Et) groups an artificial compound called "ætioporphyrin" is obtained. There are four possible isomeric ætioporphyrins, but the naturally occurring porphyrins all correspond to series I (formula B) or series III (formula C). There is no simple chemical way whereby series I compounds can derive from series III or vice versa; breakdown of the porphin nucleus and resynthesis would be needed and this is thought to be a very unlikely occurrence. The different porphyrins have different side-chains replacing the eight H atoms in porphin. Thus protoporphyrin has four—one CH_3, two $CH = CH_2$, and two $CH_2 - CH_2 - COOH$ groups. Coproporphyrin, the normal excretion form, has four CH_3 and four $CH_2 - CH_2 - COOH$ groups; uroporphyrin, with four $CH_2 - COOH$ and four $CH_2 - CH_2 - COOH$ groups appears only in the porphyrias. Now the protoporphyrin of hæmoglobin belongs to series III and Watson[1] showed that the free protoporphyrin in reticulocytes is also series III. Normal people excrete small amounts of coproporphyrin, about two-thirds in the fæces and a third in the urine; but all the fæcal and at least half the urinary coproporphyrin is series I and cannot therefore have been derived from the breakdown of hæmoglobin. Patients with hæmolytic anæmia known to be destroying large numbers of erythrocytes excrete relatively large quantities of coproporphyrin, but surprisingly this again is all series I. This unexpected finding that the excreted porphyrin is a different isomer and is therefore not derivable from the hæmoglobin porphyrin was called by Fischer the "dualism of the porphyrins" and has to be taken into account in any study of porphyrin excretion designed to throw light on hæmoglobin metabolism. It is not sufficient to know how much porphyrin is excreted—we must know to which series it belongs, and indeed Watson thinks it more important to know which than how much. Unfortunately the determination of the isomeric type is far from simple; it demands[2] the separation of the porphyrins, the preparation of their methyl esters and the determination of melting-points; and since the amounts excreted daily are measured in microgrammes, or only occasionally in milligrammes, skilled chemical technique is essential. For these reasons little data is at present available, but what there is is important.

In pernicious anæmia[3] there is greatly increased excretion of coproporphyrin I. When specific liver treatment is given the porphyrin excretion continues raised until after the reticulocyte peak is passed; then it slowly falls to normal. Coproporphyrin I is also excreted in large amounts in hæmolytic anæmia and in the period of blood-regeneration after hæmorrhage.[2] In aplastic anæmia[4] on the other hand, from a fifth to a tenth of the excreted coproporphyrin is series III, and coproporphyrin III has also been found in poisoning by lead,[2] sulphanilamide[5] and other substances. Hence the excretion of coproporphyrin I seems to be linked with unusual erythropoietic activity, including the megaloblastic erythropoiesis of pernicious anæmia, but excretion of coproporphyrin III seems linked with depressed erythropoiesis. In the first group there is always evidence of excessive destruction of red cells, but as already pointed out the coproporphyrin I cannot have come from the red cells. Is the coproporphyrin III of the second group derived from hæmoglobin? Apparently not. Lemberg's[6] studies of hæmoglobin breakdown have revealed that porphyrins are not formed; the porphin nucleus opens while still attached to globin and iron and thereafter is converted into biliverdin and bilirubin; the excretion forms of bilirubin, urobilin and urobilinogen, are therefore used as indicators of hæmoglobin destruction.

Ingenious explanations of these contradictions have been suggested by Rimington,[7] Dobriner and Rhoads,[2] and Turner.[8] They all suppose that from a pyrrolic precursor porphyrins of series I and III are formed simultaneously, normally much more III than I, but if the production of III is increased I is increased proportionately. The series III porphyrin is protoporphyrin and is used in the formation of hæmoglobin, but the series I porphyrin is apparently useless—it is converted into coproporphyrin and excreted. Hence if there is unusually rapid formation of red cells more porphyrin III is needed for hæmoglobin and a correspondingly increased amount of porphyrin I is formed and excreted. But in aplastic and toxic anæmias, owing either to the absence of erythroblasts or to toxic interference with hæmoglobin synthesis, the porphyrin III still being formed is unused and is excreted as coproporphyrin III. The changes in congenital and acute porphyrias are attributed to disturbance of this orderly synthesis. There is no real evidence in support of this theory but it fits the facts partly at least. Rimington and Hemmings[9] have shown that toxic drugs like sulphanilamide which cause methæmoglobin formation also cause increased porphyrin excretion, and this is coproporphyrin III. Hence they suggest that this may represent an alternative method of hæmoglobin breakdown, but occurring only when methæmoglobin is a phase in the cycle.



Formula A



Formulæ B and C

Clearly there is still room for much more evidence before confident interpretations are possible, but the type of problem these results can be applied to is illustrated by Vaughan and Saifi's[10] investigation into the cause of anæmia in chronic infection. The porphyrins excreted by their patients were estimated by Rimington who reported a rise in the excretion of both series I and III. Since there was no evidence of increased hæmoglobin breakdown it was concluded that a disturbance of hæmoglobin synthesis was responsible. In a previous paper,[11] by correlating cytological examination of the bone-marrow with clinical findings I was able to divide erythropoietic disturbances into broad groups. Further subdivision of these groups may well come from biochemical studies of hæmoglobin metabolism which can detect the conditions in which hæmoglobin is insufficiently available for normal marrow cells. The difficulty of the biochemical methods involved still stands in the way of really systematic investigation of the anæmias from this point of view. As Watson has said what we need is a differential method permitting estimation of the amount of each isomer present without recourse to actual isolation. Until this happy day comes we must proceed where we can, with the determination of the porphyrin isomers appearing in the various anæmias so that there will be sufficient data free from the bias of individual cases

LIGATION AND CHEMOTHERAPY FOR INFECTION OF PATENT DUCTUS ARTERIOSUS

GEOFFREY BOURNE, M D LOND, F R C P

KENNETH D KEELE, M D LOND, M R C P
O S TUBBS, M B CAMB, F R C S

Note on the bacteriology by R H A SWAIN, M B CAMB

THE dangers of a patent ductus arteriosus lie in two main factors the mechanical effect on the circulation and the local supervention of infection Gross, in 1939, first ligated a patent ductus, since when some 20 or more cases have been reported Gross and Hubbard (1939) considered that infection of the ductus contra-indicated ligation However, in view of the hopeless prognosis in infected cases, operation combined with sulphapyridine therapy was considered justifiable in the two patients here described Case 1 was the first example of successful ligation in the presence of infection yet reported (Keele and Tubbs 1940) The patient was operated on in December, 1939 Until April, 1941, when he was last heard of, he remained an active working citizen free from cardiovascular symptoms, Some hæmaturia from a coexistent nephritis persisted The second patient was similarly treated by the sulphapyridine-operation technique in October, 1940, and remains well 11 months later

CASE-HISTORIES

CASE 1 —Man, aged 23, admitted to St Bartholomew's Hospital under care of one of us (K D K) in October, 1939 Five months before had had febrile attack diagnosed as influenza, for which was kept in bed for 14 weeks, during which there was but slight improvement Weakness and loss of weight (2 st) progressed Since this illness had never felt well Periods of 1–3 weeks at work alternated with similar periods in bed Recently dyspnœa on exertion had been noticed No gross hæmaturia and no pain in chest or petechial rash had been observed No previous illness, apart from "heart trouble" from birth, this had not prevented him from playing football and cycling

Lightly built pallid man (Hb 45%) Small petechiæ over neck, shoulders and legs Cardiac impulse heaving Apex-beat 4¾ in from midline Palpation over the pulmonary base revealed thrill extending through systole into early diastole Loud "machinery" murmur heard all over præcordium, maximal in region of pulmonary base, occupying all systole and large part of diastole Pulmonary second sound audible Blood pressure labile, varying from 110/60 to 150/80 mm Hg with patient lying in bed Liver and spleen palpable A teleradiogram showed slight enlargement of heart and prominence of pulmonary conus region Red cells 2,665,000 per c mm, Hb 45%, white cells 11,300 (polymorphs 80%) Sedimentation rate, 135 mm in 1 hour Urine contained much albumin, with positive guaiacum reaction, microscopy of centrifuged deposit showed many red cells, pus cells and few granular casts, culture grew *Streptococcus fæcalis* (once only) Blood urea, 71 mg per 100 c cm Blood culture positive for *Hæmophilus influenzæ*

Course —High intermittent fever, uninfluenced by general medical treatment and blood transfusions After 2 weeks sulphapyridine begun in dosage of 3 g daily for 3 days, then 1½ g daily for 18 days until operation This small dose produced vomiting and depression, but also dramatic subsidence of fever General condition improved considerably, but blood culture remained positive In view of this it was decided, after 3 weeks' improvement, that he had a chance of surviving ligation of patent ductus, and this was carried out by O S T on Dec 5, 1939 At the moment of ligation, blood-pressure rose from 108/60 to 120/80 and murmur at pulmonary base diminished to short rough systolic murmur, which has since remained unchanged Post operative cour complicated, as expected, by further impairment of renal function, and development of uræmia Headache, vomitin and oliguria accompanied rapid rise in blood pressure to a maximum of 180/120 Blood urea at this time 218 m per 100 c cm and alkali reserve 36 6 Some œdema of neck and upper chest, subsided within 10 days

After this anxious period steady improvement ensued Sulphapyridine had not been given during this time, but nevertheless the blood culture became negative and remained so for 3½ months The hæmaturia diminished and the blood pressure slowly fell At the end of March, 1940 (3½ months), blood culture became positive again and three courses of sulphapyridine, each totalling 30 g in 10 days, were given, with a week's interval between each Since the final course the patient has remained afebrile In spite of this a further positive blood culture was obtained in June, 1940 The patient was then up and had no symptoms, volunteering that he had "never felt better in his life" Blood urea 42 mg per 100 c cm, sedimentation rate 110 mm in 1 hour Urine showed red cells and some granular casts, urea clearance 40% of normal Blood culture was negative 2 months later and has remained so since (January, 1941) When last seen (April, 1941) felt well During a short period at home permitted after 9 months in hospital, returned to work (against our advice) and got married No change in cardiac signs Short pulmonary systolic murmur persisted Blood pressure more stable at 110 Sedimentation-rate 60 mm in 1 hour Red cells 5,530,000, Hb 122%, white cells 18,000 (polymorphs 59%) Blood urea 44 mg per 100 c cm Blood culture negative after 10 days

CASE 2 —A girl of 19 who had always known that there was something wrong with her heart Remained in good health until 4 months before admission to hospital During this time complained of headache, lassitude and undue sweating at night, and fever present more or less continuously No peripheral or pulmonary embolic symptoms On admission intermittent fever present, ranging up to 100° and 101° F Apex beat 1 in to left of midclavicular line Typical systolic murmur and thrill of patent ductus arteriosus present, persisting well into diastole and loudest in second left interspace near sternum Blood pressure 132/40 Blood culture yielded, on three separate occasions, growth of *Strep viridans* in all tubes, colony count in shake culture numbering at first about 300 per c cm Red cells 3,800,000, Hb 62%, white cells 14,800

Course —After a week, 6 g of sulphapyridine per day given for 4 days, then reduced to daily dose of 4½ g for 12 days Fever disappeared and blood-cultures became less profuse and then sterile Afebrile period lasted 12 days until operation on Oct 21, 1940 After ligation of ductus (O S T) febrile reaction occurred lasting 3 days Temperature occasionally touched 99° F during subsequent 3 weeks, then kept normal for whole convalescent period Sulphapyridine continued at daily dose of 4½ g daily for 5 weeks, when reduced to 3 g for 4 days, after which it was omitted Put on a stone in weight in first month Has remained well for 11 months (September, 1941) Sedimentation rate then normal

SURGICAL TECHNIQUE *

The technique employed in these two patients was almost exactly the same as that described in detail by Gross (1939, 1940) for cases uncomplicated by infection so that a detailed description would be superfluous, the main steps in the operation will however be outlined since no similar cases have yet been reported in the English journals

Both patients received intravenous glucose saline during the operation The wisdom of this therapy is doubtful, since these people, like those with an arteriovenous aneurysm, have an increased blood-volume, and the sudden conversion of the circulation to that of the normal person therefore theoretically throws a temporarily increased burden on the heart, fluid put in artificially can only add to this increase It is an insurance again possible rapid hæmorrhage, however, but it should be stopped as soon as the ductus is successfully ligated

---

* The surgeon (O S T) wishes to acknowledge that his inter in the subject was initiated by Strieder, who made the first attemp to ligate an infected patent ductus arteriosus (Graybiel Strieder and Boyer 1938)

Anæsthesia was by a nitrous-oxide, oxygen and ether mixture (Dr C L Hewer and Dr F Evans) in case 1, and by cyclopropane and oxygen (Mr B Rait-Smith) in case 2 An endotracheal tube was used in case 1 but not in case 2 The ductus arteriosus was approached through the left pleural cavity, which was opened through the second left intercostal space, the skin incision extending from the midline in front to the anterior axillary line The second and third costal cartilages were divided close to the sternum and excellent exposure obtained by separating the ribs with a rib-spreader The internal mammary vessels were divided between ligatures so that full use of the medial end of the incision might be obtained In case 2, the two layers of pleura were adherent around the medial half of the incision and on the mediastinum and required separation by blunt dissection , the adhesions apparently resulted from infarction of the lung which was firm and red in this region In both patients, the grossly enlarged pulmonary conus was seen to distend abnormally during systole and a well-marked thrill was palpable In the first patient, the region of the ductus arteriosus was exposed by continuing the intercostal pleural incision on to the mediastinum, but it was found that the phrenic nerve and its accompanying vessels prevented adequate working room and had to be divided This was obviously an error in technique and was corrected in the second case by incising the mediastinal pleura parallel with, and posterior to, the phrenic nerve which was then retracted anteriorly No difficulty was experienced in either case in identifying the patent ductus

The cellular tissue under the arch of the aorta was gently swept from the anterior surface of the ductus with a pledget of gauze held in a long hæmostatic clamp Keeping immediately against the wall of the ductus, the adjacent tissues were readily separated by blunt dissection except from the posteromedial surface where a plane of cleavage must be found without a direct view This was done by insinuating the left index finger into the cleft between the aortic arch and the bifurcation of the pulmonary artery anterior to the ductus and passing a malleable blunt-ended aneurysm needle through the tissues behind the ductus, so as to impinge on the left index finger finally bringing the eye into view anteriorly to receive the ligature material This part of the dissection must obviously be carried out most gently, keeping close to the ductus Contrary to the experience of Touroff and Vesell (1940a), in neither case was anything but trivial hæmorrhage encountered Nevertheless, if infection is not of recent inception, the surgeon must be prepared to find the walls of the ductus thinned, friable and adherent, and possibly an associated mycotic aneurysmal dilatation—a danger which has been much stressed by American workers The recurrent laryngeal nerve was not identified in either patient, but it was thought that damage would be avoided by always keeping the dissection against the wall of the ductus It is probable that physiological conduction was interfered with temporarily in the first patient, for he was hoarse for several weeks after the operation, but full recovery was present by the sixth week, when the vocal cords were examined by Mr Norman Jory There was no interference with voice production in the second patient

The ductus was about ½ in in diameter in the first case and a little more than this in the second , in both, the length was approximately ¾ in The idea of excising the ductus appears to be excellent in theory but totally impractical Gross's comment that "the ductus has always been so short that I have not dared to divide it in any instance" applied in our two patients Two doubled no 5 tubular silk ligatures were used to occlude the ductus A faint thrill could be palpated in the pulmonary conus after applying the first ligature in each case, but it was abolished by the second Finally, the mediastinal pleura was sutured and the wound closed in layers Gentle positive pressure was used by the anæsthetist during closure of the wound so that complete reinflation of the lung expelled all the air from the pleural cavity

POINTS OF INTEREST

Physical signs after operation —In case 1 the classical signs of patent ductus arteriosus changed after ligation to a short rough systolic murmur at the pulmonary base The palpable thrill disappeared No detectable change in the size of the heart was found, though after ligation the pulmonary conus and artery seemed to be less distended during systole, being deprived of the blood regurgitated through the patent ductus After operation the blood-pressure rose from 120/80 to 180/120 and the blood-urea from 71 to 216 mg per 100 c cm , since when there has been progressive improvement in these features

In case 2, before operation the typical systolic murmur carried on into diastole had been present After ligation it persisted and remained for some weeks nearly as loud as before After 7 months it had become much less loud, the diastolic part of the sound being now nearly inaudible This curious fact was also noted by Touroff, who in one case cut the ductus between the two ligatures, thus disposing of the criticism that the persistence of the murmur might be due to imperfect obliteration of the vessel The blood-pressure, which before operation had been 132/10, rose after it to 154/122 the diastolic remaining higher than normal for 6 weeks During this time the renal function became and remained impaired, the standard urea-clearance 15 days after operation being reduced to 21 9 c cm , (29 2% of the average normal) for the first hour, and 15 2 c cm (28%) for the second hour There had been no preoperative evidence of any renal or urinary abnormality

Early diagnosis —Both these patients, known to have congenital heart disease, remained febrile for 4–5 months or more before infective endarteritis was diagnosed Case 1 had become almost moribund during this period , case 2 was in much better condition An early diagnosis is obviously desirable in cases of infection of the ductus where ligation is to be attempted Symptoms of infection are not dramatic and influenza may be diagnosed even when pyrexia is persistent In case 1 this remarkable absence of symptoms was again shown after operation when he felt perfectly well, although a positive blood-culture was obtained The same comparative well-being occurred in case 2 with the commoner *Strep viridans* as the causative organism Any patient known to have a patent ductus arteriosus who runs a fever for more than a week without obvious cause should be suspected of infection in this region and investigated accordingly In case 1 the continuance of the focal nephritis, which darkens the prognosis, can be regarded as in some degree due to delay in diagnosis Obviously the earlier operation is performed the less chance there is of renal or other complications

Diagnosis of the heart lesion —In both these patients the physical signs were typical of patent ductus arteriosus In both the high pulse-pressure and the teleradiograms were confirmatory There was no evidence of any other congenital defect, or of infective endocarditis of any valves, though such negative evidence must be of only limited value

Pathology of the lesion in relation to ligation —Maud Abbott (1936) describes the original site of infection as always being at the pulmonary end of the patent ductus This is narrower than the aortic end From here the vegetations spread over the left pulmonary artery far sooner than into the aorta Patches of vegetations are found on the wall opposite the opening of the ductus, presumably carried there by the blood-stream which flows from aorta to pulmonary artery Eventually the pulmonary valves may be involved in the spread of the vegetations Thus left-sided pulmonary infarcts are common Radiological evidence of them was seen in case 2 and a large one was found at operation There seems to be no preoperative method of establishing the length of the patent ductus If the ductus is sufficiently long, ligatures should be placed at each end, special care being taken to obliterate the pulmonary end as completely as possible Periarterial adhesion and fragility of the wall of the patent ductus accounted for fatal hæmorrhage in two of Touroff's cases (Touroff and Vesell 1940b) In our cases the ductus was easily defined, the wall appearing pink but firm No hæmorrhage occurred during the manipulations necessary for passing two silk ligatures In case 2 some oozing resulted from the fact that the inner aspect of a moderately large pulmonary infarct lay over the region of the ductus

Bacteriology —The organism isolated by blood-culture from the first case was a hæmophilus

It was a small pleomorphic non motile gram-negative coccobacillus and had no tendency to filament formation In the first instance the organism was obtained in blood cultures made in glucose broth incubated aerobically, where it appeared as small fluffy spherical masses on the surface of the blood Later it was found that growth was considerably accelerated by cultivation in air to which 10% of carbon dioxide had been added In subcultures the strain was found to lose its capacity for growth on solid media unless cultured in the presence of carbon dioxide The colonies on solid media grown in the presence of 10% carbon dioxide were small, convex, with an entire edge, translucent and non hæmolytic The organism grew well on boiled blood agar, Fildes agar, and 5% horse blood agar In 1% horse blood broth and Fildes broth the organism grew well and gave rise to a slight granularity on the side of the tube A scanty or moderate growth was obtained in the following media serum broth, peptone broth, nutrient agar, serum agar, and inspissated serum Well marked satellitism occurred when serum or plain agar cultures were weeded with a colony of *Staphylococcus albus* The organism did not grow in peptone water or in a filtered peptone water culture of *Staph albus* A growth did occur in peptone water to which X-factor in the form of hæmatin, or V-factor in the form of a heated yeast extract, had been added The following sugars were fermented mannite, inulin, dextrin, glucose, dulcite, arabnose, raffinose and salicin Maltose, lactose, saccharose and galactose were not attacked No indol was formed The organism was agglutinated to a titre of 1 in 1250 by the patient's serum, but not by agglutinating sera of *Brucella abortus*, *Br melitensis* or *H pertussis*

The morphology and cultural characteristics of this organism make exact identification difficult since it differs from *H parainfluenzæ* described by Miles and Gray (1938) in its X- and V-factor requirements and from *H influenzæ* in its biochemical reactions and affinity for carbon dioxide Professor Miles has examined the organism and confirmed these findings, he suggests that the organism is an atypical strain of *H influenzæ* resembling in its carbon-dioxide requirements *H aphrophilus* described by Khairat (1940)

Sulphapyridine therapy —Surgery would have been impossible in case 1 without previous sulphapyridine therapy, owing to the patient's very poor general condition With sulphapyridine the patient had been afebrile for 3 weeks before operation Although we have seen no case of this rare influenzal endarteritis treated with sulphapyridine alone, the likelihood of its being successful while the large mass of vegetations existed can be considered remote With *Strep viridans* infections it is well known that although temporary sterilisation of the blood-stream may be effected with sulphapyridine a fatal outcome is still nearly constant

COMMENT

Hubbard, Emerson and Green (1939), in discussing the indications for ligation of the patent ductus arteriosus, conclude that the procedure should be limited to cases "showing evidence of circulatory embarrassment," among which they include signs of severe regurgitation They doubted if ligation had any prophylactic value against subsequent infections Time alone can answer this question Gross has considered infection of the ductus a contra-indication because of the risk of producing embolism Of this we have found no evidence in these cases, and such risk as there may be will certainly be diminished by early diagnosis and treatment We are of the opinion that infection of the ductus arteriosus is a strong indication for ligation and should be combined with chemotherapy

CASE OF CRUSH INJURY WITH RECOVER

A IAN L MAITLAND, M B GLASG , F R C S E
SURGEON LIEUT COMMANDER R N V R , SURGICAL SPECIALIST,
ROYAL NAVAL AUXILIARY HOSPITAL

THE following patient received a crush injury towards the end of April, 1941 He has been under observation for four months and recovery has now progressed sufficiently to warrant publication of the findings

CLINICAL FEATURES

Healthy man, aged 40, buried for 15 hours under debris of bombed building Was lying on back with right hand and forearm raised across face Pinned by beams which pressed heavily on right arm, right side of body, right thigh and leg First came under observation about 24 hours after he was extricated, only facts known about this period are that he had passed no urine since the burial 39 hours before, and that treatment had consisted of warmth, morphia and fluids by mouth

At no time was consciousness lost, and on admission he could describe experience rationally There were signs of considerable dehydration and shock with dry and dirty tongue No evidence of internal hæmorrhage but signs of complete lesion of right brachial plexus with fullness and tenderness in right supraclavicular fossa Weals over right antecubital fossa, right side of chest, abdomen, right buttock, outer side of thigh, over both knees and on right leg ranged in diameter from 2 to 4 in and looked like superficial burns He was vomiting slightly and complained of nausea Urinary output during first 12 hours negligible, urine contained cloud of albumin, granular casts and epithelial cells, specific gravity 1016 Blood-pressure 110/90 mm Hg, blood urea 140 mg per 100 c cm

On the second day of observation he developed signs of severe pulmonary concussion with blood stained sputum, subsequent radiography confirmed the diagnosis Right forearm and thigh were swollen, especially thigh, which was tense and brawny throughout its length No effusion into knee joint, posterior tibial and dorsalis pedis pulses full and easily palpable Circumference at mid thigh 5 cm greater on right than left, and 5 cm below antecubital fold 7 cm greater on right side than left (table I)

TABLE I—INCREASE IN CIRCUMFERENCE OF LIMBS ABOVE MEASUREMENT OF NORMAL LIMB ON ADMISSION (CM) THIGH WAS MEASURED 15 CM ABOVE PATELLA (LEFT 45 CM ON ADMISSION), LEG 15 CM BELOW PATELLA (LEFT AND RIGHT 40 CM ON ADMISSION), FOREARM 5 CM BELOW ANTECUBITAL FOLD (LEFT 23 CM ON ADMISSION) *

Day	Thigh		Leg		Right forearm
	Left	Right	Left	Right	
1		5			7
3		5			7
7		2			7
12		5			7
13		4 5		2 5	7
14		5		7	7
16	2 5	9	1 8	5	7
18	5	10	4	7	7
19	2 5	7	4	8 2	7
22	5	10	3	8	7
26		6 2	pr	pr	pr
27		5	,,	,,	,,
28		3	,,	,,	,,

pr = slight œdema still present

* After the patient's recovery the circumferences of the thighs and legs were the same on the two sides The right forearm was then much wasted so that the measurement was no indication of that on admission I have measured the forearms of a number of people who, like the patient, are right handed, and find the circumference of the right averages 1 cm more than the left

The case was recognised as a crush injury as described by Beall and Bywaters,[1] with pulmonary complications and a complete lesion of the right brachial plexus

TREATMENT

At that time (April, 1941) 17 cases of this type had been described with 12 deaths [1 2] Of the fatal cases 1 died of intercurrent septicæmia, in the other 11 the fluid intake had been relatively small and principally made up of serum, concentrated serum, plasma or whole blood Since the treatment was admitted to be in the stage of trial and error

(Beall and Bywaters) a different approach was tried This was based on complete protein starvation and forced fluids Protein starvation was used because the biochemical findings in these cases suggested that more products of protein autolysis were being thrown into the circulation than the damaged kidneys could dispose of On this assumption it seemed reasonable to add no more protein to that already there until there was evidence that it could be utilised and the end products excreted Every form of protein was therefore withheld for 18 days, a low protein diet was then instituted and not till the 30th day was a normal diet free of protein restrictions allowed The pathological appearances described i the kidneys associated with a mounting blood urea and iminished urine were similar to the changes of congestive enal failure, as I have pointed out elsewhere[3] In view of his it seemed worth while to employ the usual treatment for hat condition During the first few days the intake by nouth was small and most of the fluid was given intravenously n the form of isotonic sodium sulphate solution The chart hows that despite a considerable intake of this solution no eal diuresis took place and the blood urea mounted steadily Vhen the peak of 400 mg per 100 c cm was reached on the th day it was felt that the risk of death from pulmonary edema was less than that from uræmia and fluid was pushed n by every available route Rectal fluids were tried, but wing to the uræmia were not tolerated until the 11th day, ortunately the patient was able to drink between 5–6 pints laily and thus an enormous daily intake was achieved The ntravenous solutions used in the period between the 6th and 1th days are shown on the chart Hartmann's solution was ised in the later stages because of its close similarity to blood lasma without the protein elements, in any case the need for sodium sulphate was no longer evident when the urinary output reached 2000 c cm

In view of the extensive necrosis of muscle and lesions of the adrenal cortex which had been reported, extract of suprarenal cortex was given from the start Eucortone 4 c cm was given daily for 24 days and 5 c cm daily for a further 8 days

Unfortunately the blood chlorides, were not estimated until the 15th day and the blood potassium and urinary chlorides were not estimated at all Sodium chloride was given from the 18th to the 30th days in a daily dose of gr 135 except on the 27th and 28th days when the dose was gr 270 The highest of a very irregular series of blood chloride figures occurred on the 28th day (table II)

In the later stages—6th week onwards—iron was given in massive doses It was given continuously for 7 weeks and during the last 4 liver was given as well in an endeavour to correct the persistent anæmia The appropriate drugs were used for the intercurrent complications and latterly ascorbic acid and vitamin B_1 have been used as part of a tonic regime They appear to have improved the anæmia, but whether this will be permanent is questionable

Local treatment was simple The abrasions and weals were painted with 1% crystal violet solution The affected limbs were placed in the position of rest, and as soon as possible an abduction frame was applied to the paralysed arm and physiotherapeutic treatment instituted

PROGRESS

General condition remained very poor during first 10 days, with characteristic signs of uræmia Thereafter improvement gradual and slow, with slight psychic disturbances about 18th day On 38th day bronchopneumonia developed in left lower lobe, when recovering from this acute infection of throat with hæmolytic streptococci developed Since this cleared up convalescence has been without incident Blood-pressure readings are shown in table II The blood-counts and hæmoglobin estimations in table II reveal constant degree of anæmia which is persisting despite treatment and is highly suggestive of some permanent renal damage Icteric index was estimated by Meulengracht s method on 5th, 7th and 15th days, figures were all within normal limits (2, 4 and 5 units respectively) Clotting time done on 7th day very prolonged (20 min, normal control 5 min) Method of Lee and White used and estimation not repeated

TABLE II—BLOOD-CHLORIDES, BLOOD PRESSURE, HÆMOGLOBIN AND RED CELL COUNTS

Blood chlorides*		Blood pressure (mm Hg)					
Day	mg NaCl per 100 c cm	Day	Syst	Diast	Day	Hæmoglobin (%)	Red cells (per c mm)
15	220	2	110	90	13	62	
19	500	4	125	85	15	63	2,540,000
21	500	5	110	80	21	68	
23	125†	6	120	80	43	70	3,285 000
25	100†	8	120	95	56	70	3 400,000

					102	80	3 700,000

* By Whitehorn s method

† These two results are low because the blood was allowed to stand for some hours before the estimation was done They must therefore be discounted

Urine was examined daily during first 4 weeks and varied little Specific gravity remained between 1014 and 1012 for 12 days and thereafter dropped gradually to 1004 Daily output (see chart) rose slowly to 2500 c cm on 7th day and remained around that level throughout period of observation. Urinary urea was estimated by hypobromite method using a Doremus ureometer Albumin constantly present, at first as light cloud, but after 15th day only as trace Epithelial cells present in first specimen only, thereafter for first 6 days granular and hyaline casts and red blood-cells noted Casts present for further 4 days, after that only occasional red cell seen First specimen of urine was negative to reduced phenolphthalein test and contained no red cells Urine never contained pigment and no pigment casts were observed Blood urea estimated by modification of Falen's method

---

[3] Maitland, A I L *Ibid*, p 570

Urea clearance was done 5 times and the results were as follows

Day of disease	Blood urea (mg per 100 c cm)	Av % of normal function
6	400	7
13	227	15
20	80	41
36	42	65 5
102	32	91

The swellings of right arm and right thigh were entirely different in character Arm was seat of true œdema, greatest in dependent part of upper forearm, produced by deep hæmatoma around neurovascular bundle in supraclavicular area and due to stasis in veins and lymphatics of arm It was present from the beginning and did not vary in size until it finally cleared up Swelling of thigh was not true œdema but a brawny induration which did not pit on pressure and was most firm and longest in evidence under the weals True œdema supervened later, affecting right leg first on 13th day and appearing in left leg and thigh on 16th day, some œdema also appeared over lumbar region on 22nd day (table I)

PRESENT CONDITION

Four months after injury is able to be up most of day Blood pressure 110/60, fundi normal and lungs have recovered completely No relative wasting of right thigh but muscles very weak and resultant instability has produced small effusion into knee joint Left leg can be extended indefinitely against resistance of 10 lb 32 times per min, but right leg can only be extended 18 times against resistance of 2 lb 14 times per min before fatigue supervenes, renal function has recovered almost to normal Urine normal, sp gr 1012 Anæmia persists and appears to be resistant to treatment, brachial plexus lesion is represented by recovering ulnar palsy

DISCUSSION

The most striking feature of this case is the high proportion of the large fluid intake which was retained between the 7th and 15th days During these 8 days 25 5 litres was retained without any great increase in the swelling of the limbs or the appearance of anasarca The œdema which did eventually develop did not appear till the 16th day and reached its maximum between the 19th and 22nd days This retention cannot be ascribed entirely to the administration of cortical extract and other factors in treatment, since the bulk of the fluid remained in circulation for at least 6 days It must therefore have been required as a diluent of some abnormal substance in the blood, probably a high molecular protein derived from the damaged muscle The two cases of this syndrome recently reported[4] appear to have had a similar course to the one described here Unfortunately the fluid retention, if any, in each case is not stated In one of them (Longland and Murray), however, the clinical features suggest that a true transfusion kidney cannot be excluded, since the patient had a rigor after a plasma-transfusion, followed by icterus and unaccompanied by swelling in the injured limbs

The glomeruli of the kidney are supplied with blood direct from the interlobular arteries through the afferent glomerular vessels, the tubules and loops of Henle are supplied by capillaries derived from the efferent glomerular vessels, and the collecting tubules and ducts of Bellini are supplied from the main branches of the renal vessels through the arteriæ rectæ The lesion associated with the crush syndrome is situated in the convoluted tubules and loops of Henle, and it will be seen that the blood-supply of this area comes through the reducing chamber of the glomerular capillary bed There, not only is the pressure reduced but the blood is concentrated by the loss of fluids and salts secreted by the glomerulus In the light of this knowledge a cause for the lesion suggests itself In all the cases described severe shock has been a feature This is shown by the low blood-pressures recorded In some cases both systolic and diastolic pressures have been low, in this case the systolic pressure alone was low It can be presumed that this shock has its onset when the patient is first buried and therefore is prolonged over many hours This will produce in the capillaries of the convoluted tubules a vicious circle of vascular stasis, hæmoconcentration and thus more stasis These changes will be increased by the absence of fluid intake during the buried period and the flooding of the circulation with a protein of high molecular weight from the damaged muscle There is experimental evidence[5] that a rapid elevation of blood-pressure during the recovery period may produce further tubular damage by intensifying this stasis in the vessels of the convoluted tubules

This hypothesis is supported by the following clinical evidence (1) the invariable presence of abnormality in the first specimen of urine examined, (2) the common critical point in all cases between the 6th and 8th days, (3) the fatal termination in one case despite amputation of the crushed limb, and (4) the recovery of two severe cases with general measures only during the first 24 hours followed by the usual treatment of congestive renal failure The conclusion is that this lesion is produced primarily by the long period of lowered blood pressure or pulse-pressure aggravated by the absence of fluid intake during part of that time and the presence of an excess of a circulating protein derived from the damaged muscle It is in fact an active congestive renal failure with a possible toxic element superimposed and it may be intensified by too rapid elevation of the blood pressure, particularly if that elevation is produced by plasma or concentrated serum The experience of this condition is limited and the theory outlined requires more evidence for its proof, but it seems reasonable and worth further investigation by animal experiment and clinical observations

The lesions described in the adrenal cortex in two reported cases and the irregular behaviour of the blood chlorides in the present case despite a constant dose of cortical extract and sodium chloride suggest that some similar changes to those in the kidney may take place in the suprarenal cortex They certainly point to the necessity for examining the blood and urinary chlorides from the start in these cases

SUMMARY

A man, aged 40, developed severe renal failure as a result of burial for 15 hours under a bombed building He was pinned across the right thigh and right side of the trunk He also had a lesion of the right brachial plexus and pulmonary concussion

He was treated by complete protein starvation and forced fluids, with injections of suprarenal cortical extract A large proportion of the fluid was retained between the seventh and fifteenth days without any corresponding increase in the œdema, though a general anasarca was present from the sixteenth to the twenty eighth day

Improvement began on the tenth day, and four months after the injury the patient appears to have made a good recovery, in spite of an intercurrent bronchopneumonia and a streptococcal infection of the throat An anæmia persists in spite of treatment, which suggests some renal damage not evident to tests of function, and the affected thigh, though anatomically normal, has lost almost all it extensor power

It is suggested that in such cases the renal failure is caused by vascular stasis due to lowered blood-pressure from the time of the injury, to the lack of fluid intake during the period of burial, and to flooding of the circulation with protein from damaged muscle The lesion in the kidney may be aggravated by transfusion with plasma or concentrated serum

I have to thank Surgeon Rear Admiral F J Gowans for permission to publish this case, Surgeon Commander R S Allison for his help and criticism during the treatment of the case and preparation of this paper, and C P O Webster and the staff of the clinical laboratory for the estimations

MEDICAL DEFENCE UNION —The annual meeting of this society was held on Sept 30 Dr G de Bec Turtle, acting president, who was in the chair, said that the membership was now over 24,000 War had not decreased litigation and he urged doctors to exercise great care in signing medical certificates Dr Turtle was elected president for the coming session

CYCLOPROPANE ANÆSTHESIA

R BLAIR GOULD, M B SHEFF, D A
HONORARY ANÆSTHETIST TO GOLDEN SQUARE THROAT HOSPITAL, SPECIALIST ANÆSTHETIST IN THE E M S

MANY papers have appeared on the pharmacological and physiological aspects of cyclopropane I shall here deal with the application of this knowledge to its administration as an anæsthetic, in the light of experience I have gained during the past few years

Perhaps in no other type of anæsthesia is the apparatus used of such importance, for an inaccurate, leaking, inflexible apparatus will make for failure, and greatly add to the difficulties of the administrator The principles of an ideal apparatus have been described by Harris (1933, 1935, 1938), and I agree with him in favouring the circle filter as against the to-and-fro principle of Waters (1932) Although the latter has the advantages of portability and simplicity it is difficult to handle the irritant soda-lime is too near the face-piece, greatly increasing the danger of its inhalation · while the heat induced in the canister directly affects that part of the gas mixture which is immediately inhaled On the other hand the circle filter if correctly designed provides a flexible apparatus which more closely satisfies physiological requirements, and with an adequate canister can produce a more complete absorption of carbon dioxide In contrast to the method practised by most anæsthetists, I find that less resistance to respiration is produced when the canister is placed on the inspiratory side of the circuit, and this clinical impression is supported by manometric readings of the resistance induced in various types of apparatus at the face-piece end of the circuit

Sensitive directional valves, offering the minimum respiratory resistance, are a necessity. They should be designed to work efficiently with the reduced tidal respiration met with in deep anæsthesia They should be placed as close to the face-piece as possible, for theoretical considerations, fully explained by Harris, demand that the dead space between the unidirectional valves and the alveoli should be less than the volume of the smallest tidal respiration (Placing these valves on the machine takes no account of the expansile nature of the long rubber tubing between the valves and face-piece and permits excessive re-breathing, especially when pulmonary ventilation is reduced) This ideal is almost impossible to attain, but the closer it is approached the less will be the respiratory embarrassment, the smoother the anæsthesia, and the less fatigued the patient at the end of a long operation *

ESTIMATION OF DEPTH

he quietness of the breathing under cyclopropane is not so much to the carbon-dioxide method of ministration as to the depressant effect of the gas on respiratory centre The usual signs of anæsthesia seen with ether are not helpful, and estimation of pth is difficult Passage through the first two stages ery rapid and no excitation of respiration is seen even nduction ; in the third stage a slight and progressive rease in rate and tidal volume occurs, until intercostal alysis is complete , a small increase in concentration l now cause respiratory arrest

Vaters (1936) has shown how the patient may pass ough the third stage without manifest signs except a dual diminution in respiratory movement The rease in rate and depth of respiration which usually urs with other agents just before respiratory arrest is ght or lacking with cyclopropane, which makes it ficult to differentiate the pre-apnœa level Attention detail is therefore essential Romberger (1935 1937) d Guedel (1937) have described a system of anæsthetic ns but these are not complete, because they fail to take o account the phenomenon of general muscular axation , they are also often difficult to assess, pecially in cases where the respiratory threshold has en elevated by preoperative drugs

I find the following simplified scheme (worked out th reference to the respiratory signs only) satisfactory for teaching purposes Where planes of anæsthesia are referred to in this paper this scheme is to be understood.

Third stage	*Signs*
First plane	Light anæsthesia , moving eyeballs
Second plane	
(Upper)	Moderate anæsthesia , fixed eyeballs , intercostal paresis absent or partial only
(Lower)	Deeper anæsthesia , intercostal paralysis becoming complete (The diaphragmatic movement is not exaggerated as it is with ether)
Third plane	Intercostal paralysis has developed gradually and progressively, without any change in the character of the breathing, which is now almost entirely diaphragmatic A slight increase in concentration now leads to
Fourth plane	Apnœa, at first with no signs of circulatory depression This rapidly passes into
Fourth stage	Apnœa with circulatory depression , impending cardiac failure and death

It will be seen that the depth of anæsthesia is reflected with great accuracy by the extent of depression of breathing, and this may be used as a more accurate and easily determined method of estimating the "plane level" during the third stage than an attempt to assess the degree of paralysis of the intercostal muscles The exact points where intercostal paralysis begins and becomes complete (which mark the upper and lower limits of Guedel's third plane) are often impossible to determine in practice More useful information can usually be obtained from observation of the breathing bag and manometer than from palpation of the chest wall.

The general phenomena of anæsthesia—loss of consciousness and reduction or abolition of the reaction to pain—are due solely to the action of the anæsthetic agent on the brain Estimation of depth of anæsthesia as taught to generations of students, depends on the effect on the respiratory function Muscular relaxation, in which the surgeon is more interested appears to depend on diminution of skeletal-muscle tone as the centres in the C N S become depressed ; and in particular on depression of the anterior horn cells of the spinal cord, and suppression of stimuli normally reaching these cells from the cerebrum, cerebellum, basal ganglia skin, joints and muscles (Beecher 1938, Yandell Henderson 1935a and b, 1937, Samson Wright 1940) As a rule cord-reflex arcs are suppressed early in the third stage of anæsthesia, but it is not always easy, at any rate with cyclopropane, to correlate the degree of depression of muscle tone with the degree of depression of respiratory activity. There is evidence that there may be variation, not only between anæsthetic agents but also between patients (Magnus, R quoted by Henderson 1933) With cyclopropane, apnœa may occur before relaxation—i e , the respiratory centre may be paralysed before the cord-reflex arcs are depressed sufficiently to give relaxation—and it is important to prevent this

The drug is certainly difficult to administer in cases where deep surgical relaxation is required Diaphragmatic quietude is always present and the rapid, panting, jerky movements which are such a source of embarrassment to the surgeon with ether are not seen The peritoneum is always easily relaxed, and the intestines are not distended (as they are with the patient under nitrous oxide, which is apparently excreted into the intestinal lumen)

Animal experiment shows that with cyclopropane intestinal tone is increased and the gut is contracted, while the amplitude of contractions is reduced and propulsive movements abolished (Peoples and Phatak 1935, Burstein 1938, Weisel et al 1938) These signs may, however be present with some degree of muscular rigidity and to abolish this while keeping the cerebral concentration below apnœa level is not always easy In my experience, this may most readily be accomplished with safety to the patient by the technique of slow induction presently to be described This is facilitated by the reduction of preoperative sedation to a minimum

Since the C N S constitutes only about 5% of the total adult body-weight the anæsthetic is distributed between a small bulk of tissue upon which it has physiological action, and a far larger bulk of tissues upon which it has

---

Special valves which I have designed modified from a pattern kindly supplied to me by Dr Harris and which are sensitive to very low minute volume respiratory exchange, do, I believe closely satisfy these criteria

Urea clearance was done 5 times and the results were as follows

Day of disease	Blood-urea (mg per 100 c cm.)	Av % of normal function
6	400	7
13	227	15
20	80	41
36	42	65 5
102	32	91

The swellings of right arm and right thigh were entirely different in character Arm was seat of true œdema, greatest in dependent part of upper forearm, produced by deep hæmatoma around neurovascular bundle in supraclavicular area and due to stasis in veins and lymphatics of arm It was present from the beginning and did not vary in size until it finally cleared up Swelling of thigh was not true œdema but a brawny induration which did not pit on pressure and was most firm and longest in evidence under the weals True œdema supervened later, affecting right leg first on 13th day and appearing in left leg and thigh on 16th day, some œdema also appeared over lumbar region on 22nd day (table I)

PRESENT CONDITION

Four months after injury is able to be up most of day Blood pressure 110/60, fundi normal and lungs have recovered completely No relative wasting of right thigh but muscles very weak and resultant instability has produced small effusion into knee joint Left leg can be extended indefinitely against resistance of 10 lb 32 times per min, but right leg can only be extended 18 times against resistance of 2 lb 14 times per min before fatigue supervenes, renal function has recovered almost to normal Urine normal, sp gr. 1012 Anæmia persists and appears to be resistant to treatment, brachial-plexus lesion is represented by recovering ulnar palsy

DISCUSSION

The most striking feature of this case is the high proportion of the large fluid intake which was retained between the 7th and 15th days During these 8 days 25 5 litres was retained without any great increase in the swelling of the limbs or the appearance of anasarca The œdema which did eventually develop did not appear till the 16th day and reached its maximum between the 19th and 22nd days This retention cannot be ascribed entirely to the administration of cortical extract and other factors in treatment, since the bulk of the fluid remained in circulation for at least 6 days It must therefore have been required as a diluent of some abnormal substance in the blood, probably a high molecular protein derived from the damaged muscle The two cases of this syndrome recently reported[4] appear to have had a similar course to the one described here Unfortunately the fluid retention, if any, in each case is not stated In one of them (Longland and Murray), however, the clinical features suggest that a true transfusion kidney cannot be excluded, since the patient had a rigor after a plasma-transfusion, followed by icterus and unaccompanied by swelling in the injured limbs

The glomeruli of the kidney are supplied with blood direct from the interlobular arteries through the afferent glomerular vessels, the tubules and loops of Henle are supplied by capillaries derived from the efferent glomerular vessels, and the collecting tubules and ducts of Bellini are supplied from the main branches of the renal vessels through the arteriæ rectæ The lesion associated with the crush syndrome is situated in the convoluted tubules and loops of Henle, and it will be seen that the blood-supply of this area comes through the reducing chamber of the glomerular capillary bed There, not only is the pressure reduced but the blood is concentrated by the loss of fluids and salts secreted by the glomerulus In the light of this knowledge a cause for the lesion suggests itself In all the cases described severe shock has been a feature This is shown by the low blood-pressures recorded In some cases both systolic and diastolic pressures have been low, in this case the systolic pressure alone was low It can be presumed that this shock has its onset when the patient is first buried and therefore is prolonged over many hours This will produce in the capillaries of the convoluted tubules a vicious circle of vascular stasis, hæmoconcentration and thus more stasis These changes will be increased by the absence of fluid intake during the buried period and the flooding of the circulation with a protein of high molecular weight from the damaged muscle There is experimental evidence[5] that a rapid elevation of blood-pressure during the recovery period may produce further tubular damage by intensifying this stasis in the vessels of the convoluted tubules

This hypothesis is supported by the following clinical evidence (1) the invariable presence of abnormality in the first specimen of urine examined, (2) the common critical point in *all* cases between the 6th and 8th days, (3) the fatal termination in one case despite amputation of the crushed limb, and (4) the recovery of two severe cases with general measures only during the first 24 hours followed by the usual treatment of congestive renal failure The conclusion is that this lesion is produced primarily by the long period of lowered blood pressure or pulse-pressure aggravated by the absence of fluid intake during part of that time and the presence of an excess of a circulating protein derived from the damaged muscle It is in fact an active congestive renal failure with a possible toxic element superimposed and it may be intensified by too rapid elevation of the blood pressure, particularly if that elevation is produced by plasma or concentrated serum The experience of this condition is limited and the theory outlined requires more evidence for its proof, but it seems reasonable and worth further investigation by animal experiment and clinical observations

The lesions described in the adrenal cortex in two reported cases and the irregular behaviour of the blood chlorides in the present case despite a constant dose of cortical extract and sodium chloride suggest that some similar changes to those in the kidney may take place in the suprarenal cortex They certainly point to the necessity for examining the blood and urinary chlorides from the start in these cases

SUMMARY

A man, aged 40, developed severe renal failure as a result of burial for 15 hours under a bombed building He was pinned across the right thigh and right side of the trunk He also had a lesion of the right brachial plexus and pulmonary concussion

He was treated by complete protein starvation and forced fluids, with injections of suprarenal cortical extract A large proportion of the fluid was retained between the seventh and fifteenth days without any corresponding increase in the œdema, though a general anasarca was present from the sixteenth to the twenty eighth day

Improvement began on the tenth day, and four months after the injury the patient appears to have made a good recovery, in spite of an intercurrent bronchopneumonia and a streptococcal infection of the throat An anæmia persists in spite of treatment, which suggests some renal damage not evident to tests of function, and the affected thigh, though anatomically normal, has lost almost all its extensor power

It is suggested that in such cases the renal failure is caused by vascular stasis due to lowered blood-pressure from the time of the injury, to the lack of fluid intake during the period of burial, and to flooding of the circulation with protein from damaged muscle The lesion in the kidney may be aggravated by transfusion with plasma or concentrated serum

I have to thank Surgeon Rear Admiral F J Gowans for permission to publish this case, Surgeon Commander R S Allison for his help and criticism during the treatment of the case and preparation of this paper, and C P O Webster and the staff of the clinical laboratory for the estimations

[5] Miller, H *Brit med J*. 1941, 1 685

MEDICAL DEFENCE UNION—The annual meeting of this society was held on Sept 30 Dr G de Bec Turtle, acting president, who was in the chair, said that the membership was now over 24,000 War had not decreased litigation and he urged doctors to exercise great care in signing medical certificates Dr Turtle was elected president for the coming session they leave behind no ill effects They are not accompanied by circulatory deterioration, provided that hypo-oxidation is avoided Histotoxic anoxæmia does not appear to be a complication of cyclopropane anæsthesia provided a sound technique is employed The pulse must be continuously examined so that this condition can be recognised early, when it may be readily abolished by increasing the oxygen concentration The use of adrenaline or other sympathomimetic drug should be avoided with cyclopropane (Orth et al 1939, Meek 1940)

Excess Oxygen —Cyclopropane is administered in an atmosphere of 70–80% oxygen Beecher (1938) states that "there is no doubt that many of the toxic signs and symptoms elicited in man and animals by high oxygen concentrations are frequently seen after anæsthesia in which excess oxygen has been given," and concludes, "one may question the wisdom of administering high percentages of oxygen in anæsthesia for any length of time, at any rate to patients who are recumbent, cachectic, old or otherwise poor risks"

These toxic signs are said to include congestion of the lungs, with thickening of the alveolar walls and the presence of definite inflammatory changes, as shown by eosinophil cells therein (Haldane and Priestley 1935, Binet 1939, Behnke 1940) Horn 1938, Bonham 1939a, and Griffith 1938, have described cases of acute respiratory embarrassment resembling allergic phenomena and even acute pulmonary œdema in the course of cyclopropane anæsthesia, these have been attributed to the use of excessive concentrations of oxygen In the light of more recent experience of oxygen therapy, however, there is some difficulty in justifying such statements Boothby (1938, 1939), for example, has described the practice at the Mayo Clinic where oxygen in high concentrations has been administered to many patients every 3 or 4 hours for as long as four days, with intermissions of a few minutes only, without any evidence of pulmonary irritation

The oxygen content of arterial blood is increased by only 10–15% as a result of inhaling 100% oxygen, this amount, though negligible where the circulation is normal, has a significant effect in preventing tissue anoxia and in improving the general condition of patients whose circulatory system is depressed by shock, cachexia or old age (Card et al 1940) In my experience, cyclopropane, because of the atmosphere of excess oxygen with which it can be administered, is one of the most valuable anæsthetic agents we possess for such cases (cf Frias 1939)

Postoperative Pulmonary Complications, though fewer than are usual with ether, were not entirely eliminated in my series Apparently this has been common experience (Stiles et al 1934, Moffitt 1936, Taylor et al 1937, Schmidt and Waters 1935) The hope that lack of irritant properties in cyclopropane would materially reduce these complications was not founded on sound reasoning, for with spinal anæsthetics, for example, as with other types of local or regional anæsthesia, no direct irritation to the lungs can occur, and yet pulmonary complications are fairly common sequelæ Pulmonary postoperative complications are probably due to a combination of prolonged depression of body tone and pulmonary atelectasis (Fine et al 1938, Coryllos and Birnbaum 1932, Boland and Sheret 1928, Duff 1939, Burford and Jones 1938, Griffith 1934, Leuth 1938) Irritation of the lungs by the war gases produces œdema, a totally different pathological condition from that following operations Spinal anæsthesia abolishes completely the tone in those parts of the body anæsthetised, and in many cases over the whole body, and this explains the frequency of pulmonary sequelæ There is therefore little ground, if any, left for the belief once general, that irritation of the lungs by the vapour of ether or other volatile anæsthetics is the cause of pulmonary complications after inhalational anæsthesia The underlying cause is atelectasis—alike after spinal, local, intravenous or inhalational anæsthesia—due to diminished body tone and subsequent collapse of the lungs (Yandell Henderson 1935a, b, 1936 and 1937, and Ayre 1938)

The improved postoperative condition of patients after anæsthesia with cyclopropane is due to the comparatively non-toxic nature of this drug, the ease with which depth of anæsthesia may be varied at will, so that profound muscular atonia is not maintained over long periods, and the rapid recovery of consciousness and body reflexes, accompanied by a similarly rapid recovery of muscular tone, which occurs unless operative shock has been severe This rapid recovery, although always desirable (Harms 1939), sometimes proves embarrassing After cyclopropane the prolonged stupor and inertia seen after the older anæsthetics does not occur Displacement of nitrogen, however, is a real danger, and care must be taken before the anæsthetic is withdrawn, to restore a more normal alveolar atmosphere Barach (1935a, b, 1936) Bonham (1939b), Eversole (1938) and Burford (1938) have suggested that helium, which is very slowly diffusible, should be added to the gas in the closed circuit machine Helium though easily obtainable in America is difficult to obtain in this country, and I have been unable to get experience of this technique Other precautions must be taken The anæsthetic must not be withdrawn until the respiratory ventilation is again active and adequate The lung bases may be aerated, the tone of the respiratory muscles increased and lost nitrogen be replaced to some extent at least, by the inhalation towards the end of the operation of a mixture of carbon di-oxide and air (not oxygen), often this may be continued with advantage for five minutes every hour, for some hours, during the recovery period By these means the incidence of postoperative lung complications may be reduced

CONCLUSIONS

The final assessment of cyclopropane as an anæsthetic has yet to be made No attempt has been made to compare results of the 500 cases on which this paper has been based with those obtained with any other anæsthetic agent In my opinion some hundreds of thousands of cases would be necessary in order to do this with any approach to accuracy, since conditions vary so much from hospital to hospital, surgeon to surgeon, and anæsthetist to anæsthetist But some propositions may be formulated on the experience gained

1 Cyclopropane produces a smooth induction without excitement, and quiet, even, breathing, with *no irritation of* mucous membranes It is associated with a high oxygen content of the anæsthetic atmosphere which is of value in many cases

2 Depth of anæsthesia is under direct and easy control, and muscular relaxation is usually excellent

3 It produces safe anæsthesia without anoxæmia, carbon dioxide accumulation or irregular, struggling, respiratory movements, even in patients whose vital capacities are limited by disease It is relatively non-toxic to body cells

4 There is a rapid return of consciousness, of the cough and other reflexes, and of general body tone Postoperative nausea and vomiting are decreased, and anæsthetic shock reduced Compared with ether, the postoperative state is more pleasant to the patient and more satisfactory to the surgeon

5 Many of the cases in this series were suffering from acute respiratory disease of one form or another, and the post operative results in these cases were excellent—in most of them some form of local or regional analgesia was the only alternative

6 Although the expense of cyclopropane and of its apparatus is greater than of other routine anæsthetic drugs, the saving in postoperative convalescence makes this worth while

On the other hand, there are some drawbacks the gas forms an explosive mixture with oxygen, there is more operative bleeding, and transient cardiac arrhythmias occasionally develop which, however, do not appear to be of great significance The technique is complicated, and the drug is not one to be administered lightheartedly by the tyro Close attention to detail is essential, and the margin of safety is probably less than with ether The advantages of cyclopropane over ether, however, far outweigh, in my opinion, any possible disadvantages It may be objected that theoretical considerations have been given a disproportionate place in this paper, but I believe that understanding of underlying principles must always precede practical advances

Closer alliance of the anæsthetic departments of hospitals with the pharmacological and physiological virtually none Thus the concentration of the drug in the nervous system will be influenced by its solubility in the rest of the tissues This buffering action of the body tissues delays both induction and elimination With cyclopropane primary saturation †—that is, equilibrium between lungs, blood and brain—occurs quickly, at a time when concentration in other body tissues is minimal (Barbour 1936, Waters 1936, Robbins 1937) Thus it is possible to reach a brain concentration sufficiently high to cause apnœa, while the body tissues generally are almost completely unsaturated With cyclopropane given in a completely closed system, after primary saturation has been reached a relatively high alveolar concentration must be maintained in order to keep the arterial tension at an anæsthetic level, since diffusion will gradually occur into the other body tissues The extent of this diffusion can be estimated from finding of Orcutt and Seevers (1937) that the body fat will hold, under conditions of equilibrium, about seven times as much of this gas as the other body tissues

TECHNIQUE

Induction —The following considerations must be borne in mind about induction with cyclopropane

1 Absence of irritation and rapidity of absorption in the central nervous system allow a smooth induction without respiratory stimulation and usually without excitement

2 A high degree of respiratory depression can be easily induced at an early stage in anæsthesia, and indeed at any stage, but this bears no relation to the degree of muscular relaxation produced

3 Depression of spinal cord reflex arcs (and hence muscular relaxation) can be achieved without the production of prolonged apnœas if the principles on which body saturation depends are remembered

4 Until an appreciable body saturation has been built up, the absorbing capacity of the inert tissues is so great that it is often impossible to get relaxation without producing considerable depression of the respiratory centre, and even prolonged apnœa This is by no means invariably safe

5 The high oxygen content of the anæsthetic atmosphere is not incompatible with severe anoxæmia if pulmonary ventilation becomes inadequate

For these reasons, I find a slow induction with small rate of flow of gas satisfactory, though this is contrary to the practice usually advocated (Bonham 1937, Griffith 1935, Rowbotham 1935) I continue with a flow of about 100 c cm per minute or less until respiration becomes almost imperceptible The extra time required is not appreciable Should apnœa occur at the end of this slow induction it is usually short and gives rise to no anxiety, for the fatty tissues, at this time relatively poorly saturated, provide a safety valve, and redistribution rapidly takes place Alveolar concentration is maintained by a continuous trickle of a very small flow of gas, the object being to build up a concentration in the tissues which, while remaining below the apnœa level, will depress the motor system sufficiently to produce muscular relaxation The bag should contain only enough gas to accommodate tidal respiration, it is better not to allow the breathing bag to become distended with an accumulation of gases of unknown relative composition (Burford 1936) Variation in the flow of cyclopropane or of oxygen then quickly shows itself in a lightening or deepening of the anæsthesia, collapse or distension of the bag, and maintenance of an even anæsthesia is facilitated Manometric observations at the face-piece end of the apparatus show that distension of the bag unduly increases the pressure within the apparatus, thus increasing the load on the respiratory system

Maintenance —Redistribution of cyclopropane, its diffusion through the skin and rubber components of the apparatus, loss through the open wound and in blood spilt during the operation, and inevitable leakage, cause a progressive lightening of the anæsthesia Inaccurate delivery of oxygen may enhance this effect Unless the patient is closely observed the quiet breathing in all planes makes alteration in depth of anæsthesia easy to miss, particularly as, in ascending anæsthesia, eyeball movements do not always recur to mark the return of th first plane There is a point in descending anæsthesia, at the upper part of the first plane, where vomiting may occur if the anæsthetic is not deepened rapidly, th breathing at this point is shallow If the patient i allowed to reach this point again during ascendin anæsthesia the breathing may become imperceptible or cease altogether, which leads to confusion with the third plane Apart from alterations in respiratory volume there is no satisfactory sign to warn against too light anæsthesia until the swallowing reflex becomes active, fo muscular relaxation, once produced, does not always disappear at the same rate as the respiratory function recovers Ascending anæsthesia may best be assessed by observation of the manometer attached to the breathing bag, this, in my opinion, should form an essential part of every closed circuit machine (Harris 1938)

Apnœa —The high oxygen concentration possible with this anæsthetic gives the anæsthetist a feeling of confidence, and the ease with which apnœa can be produced, with associated stillness of the diaphragm, is very striking To produce " controlled respiration " by inducing acapnia is easy, muscular relaxation, however, is not invariably produced by such techniques, nor can they be employed in every case without risk

The possible harmful effect of the indiscriminate production of prolonged apnœas is illustrated by a fatality I have already reported (Gould 1939), and is supported by much experimental evidence Robbins and Baxter (1937) found that during periods of apnœa in dogs, though the mixture in the breathing bag contained adequate oxygen, the arterial oxygen concentration rapidly fell In a typical experiment, the arterial oxygen concentration fell from 20 vols % to 2 vols % during 20 minutes' apnœa

Lengthy inadequate ventilation can bring about a state of anoxæmia, notwithstanding the high oxygen concentration in the apparatus, and considerable damage may be caused to the brain and heart Gebauer and Coleman (1938) and Henson (1937) record cases of encephalopathy after cyclopropane due apparently to nerve-cell deprivation of oxygen, in spite of the high concentration of oxygen available Schreiber (1939) and Courville (1939) have drawn attention to the untoward effects of unsuspected anoxia which may develop during anæsthesia unless careful and continuous observation is maintained In shocked, cachectic, poor-risk patients, and those with decreased cardiac reserve production of apnœa is contra-indicated Individual susceptibility and cardiac reserve are not invariably easy to assess before operation By avoiding heavy preoperative medication, muscular relaxation can usually be produced by the slow-induction technique without the production of potentially dangerous apnœa

COMPLICATIONS

Cardiac Irregularity —The cause of the cardiac irregularities observed with this drug is obscure Seevers (1934), Robbins and Baxter (1937) attributed their onset to the anoxia which may develop durin apnœa Anoxia undoubtedly plays a major rôle, but does not offer a complete explanation Kurtz (1936) Meek and others (1937) and Eversole (1937) have described effects which they attribute to a direct toxic action of the drug on cardiac tissue Robbins and Baxter (1937), and Robbins (1940a, b) describe the effects as invariably arising in animals when morphia i used as a premedicant, and less frequently when barbiturates are substituted Intravenous injection of amytal abolished the bradycardia and arrhythmia which developed in their experimental animals at the time of, or soon after, respiratory arrest (Robbins, Baxter and Fitzhugh 1939) They conclude that morphine enhance, and barbiturates neutralise, the simulating effect of cyclopropane on the parasympathetic system (Robbin 1939, Adriani et al 1940) These findings accord with clinical experience

The exact significance of these cardiac irregularitie cannot be assessed at present, but animal experiment support the clinical observation that, however produced they disappear spontaneously as the anæsthetic concentration is reduced by increasing the oxygen concentration and improving the respiratory ventilation, and that

---

† The terms " primary," "secondary " and " tissue " saturation have unfortunately become identified with the technique described by McKesson (1926) who used the first term to signify ' induction,' and the others to describe his method of obtaining profound anæsthesia with nitrous oxide by producing a high degree of anoxæmia The meanings are not to be so understood in the present paper

First operation —Preliminary medication, 1 c cm of Omnopon and hyoscine (Roche), gas and oxygen anæsthesia There was slight tissue œdema and a little clear fluid in the peritoneal cavity At the site of the previous gastro-enterostomy there was a large anastomotic ulcer, adherent to the colon near the splenic flexure, which had ulcerated through nto the colon The colon and small intestine were clamped and dissected free, the anastomosis and fistula being opened The edges of the opening into the stomach and the small and large intestine contained dense ulcer tissue which was cut away The colon was repaired by transverse suture and a piece of omentum was stitched over the suture line The edges of the openings in the stomach and small intestine were dissected free of ulcer tissue and the anastomosis was reconstituted The patient stood the operation well and intestinal peristalsis continued throughout

At 6 P M 200 c cm of 10% dextrose solution and 4 units of ordinary insulin were given intravenously and a similar amount at 9 P M On May 14 at 11 A M 250 c cm of 10% dextrose with 4 units of insulin were given intravenously and thereafter 3½ oz of milk and 3½ oz of water were given by mouth and 10 units of insulin were injected, followed by similar amounts 2 hourly with 2 units of insulin On the 15th 7 oz of milk with 6 units of insulin were given 4 hourly, thereafter solid food was added until, on May 21, he was receiving 2100 calories with ordinary insulin units 30, 25, 20 On the 28th analysis of stools showed total fat 36 5%, free fatty acid 4 9%, neutral fat 8 7%, soaps 22 9% The total blood-calcium was 12 1 mg and plasma phosphorus 4 2 mg per 100 c cm There was thus a substantial postoperative improvement in the condition of the bowel in relation to the absorption of fat, calcium and phosphorus Recovery was uneventful, and the patient was discharged on June 8 on the same diet with insulin 20 units daily and zinc protamine insulin 30 units daily

Progress —After his discharge he felt well and was at work until the beginning of November, 1940, when one morning on his way to work he experienced severe mid-epigastric pain which then moved down to the umbilicus The pain often recurred at irregular intervals not directly related to meals, it was relieved by food and alkalis At times it radiated round to the back, it was aching in character and varied in intensity There was no nausea and no vomiting His diabetic condition remained unchanged, and he was stable on 20 units of zinc protamine with 20 units of ordinary insulin every morning He was readmitted to hospital on Nov 4, 1940 The sudden reappearance of the pain suggested that the repair operation had broken down The stools were examined and showed a total-fat content of 31 2%, free fatty acid 11 36%, neutral fat 8 25%, fatty acids combined as soaps 11 6% Blood red cells 5,600,000, Hb 96%, white cells 17,300 (polymorphs 71%) Thus, since May 28, the stools had become almost normal, and the red cell count normal, although no iron had been administered Together these findings indicated considerable improvement in absorption A barium enema was administered, and Dr M H Jupe reported the presence of a gastro-entero colic fistula

In contrast with his condition on his first admission, he was n good general health, and little extra preparation was required before operation On Dec 2 he had his usual breakast, with 10 units of ordinary insulin, and 10 units of zinc protamine insulin (half his usual dosage), he had his usual dinner, an easily digestible meal, at noon At 2 P M his blood-sugar was 0 33 mg, and he received no further solid ood, he was given 2 oz of glucose in ½ pint of orangeade, with 4 units of insulin, at 2 P M followed every hour by a imilar amount of orangeade and glucose until 10 P M In view of the high blood sugar revealed at the 2 P M test, 2 units of insulin were given at 4 P M, blood sugar at 30 P M was 0 29%, so a further 24 units of insulin was given t 8 P M Nothing but water was given by mouth after 0 P M At 9 A M on Dec 3 the blood sugar was 0 22 mg An ntravenous drip of 10% dextrose was given at the rate of 0 drops per min. until 2 30 P M Blood sugar at 1 30 P M was 0 25 mg This fulfilled our desire to maintain the value ather high in view of the anticipated severity of the operative measures necessary

Second operation —This was carried out at 3 P M Premedication was again 1 c cm of omnopon and hyoscine and the anæsthetic gas and oxygen A mass of adhesions was ound to be matting the splenic flexure of the colon to the posterior aspect of the previous gastro enterostomy The gastro-enterostomy was displayed by separating the adheions The adjacent portions of the gut forming the fistula were divided, exposing the lumens of the portions of the tract involved—the jejunum with a small part of the stomach and the splenic flexure of the colon The colon was clamped with light clamps some distance from the opening, later two more clamps were applied closer to the hole An ulcer could be palpated in the wall of the colon on the distal part of the splenic flexure, and resection was considered essential Some 5 in of colon were excised and with some difficulty the two ends of the bowel were brought together and an end to-end anastomosis performed The original gastro enterostomy was repaired, the edges of the orifice were excised, and the edges sutured with continuous catgut and then inverted with a continuous seromuscular Lembert suture

Immediately after the operation the patient showed signs of shock, and a pint of normal saline was administered intravenously followed by a pint of citrated blood He rallied satisfactorily, and his subsequent progress was uneventful The postoperative regime was similar to that after his first operation A barium enema on Jan 7, 1941, showed the colon to be large but without any defect in it On Dec 20 his serum calcium was 10 4 mg and serum phosphorus 3 5 mg per 100 c cm Blood sugar estimations 2 hourly on the day before his discharge showed a slight nocturnal rise on 25 units of zinc protamine insulin and 10 units of ordinary insulin, so he was discharged on a dosage of 30 units zinc protamine insulin and 15 units of ordinary insulin each morning, his diet consisting of 2100 Calories He was discharged on Jan 18, 1941, having gained 13 lb since his operation

DISCUSSION

One seldom has an opportunity of treating a case of gastro-colic fistula so soon after its occurrence Indeed, in this case, but for the concomitant diabetes and the consequent upset in insulin balance, it might have remained unsuspected for some time

Various authors (Verbrugge 1925, Strauss 1921, Castle et al 1930, Camp 1930, Poynton and Macgregor 1930, Fairley and Kilner 1931, Mindline and Rosenheim 1935, Benker and Hammett 1939, Bennett and Hardwick 1940) have drawn attention to the clinical features of the condition The symptoms are usually those of ulceration, either simple or malignant, of the stomach followed in the former case by gastro-enterostomy and subsequent anastomotic ulcer, and in the latter by direct spread by intestinal ulceration The patient may complain of foul eructations (in our case this symptom was elicited only by inquiry), of loss of weight although the appetite is good, and of diarrhœa, there being sometimes as many as 10–12 motions in the 24 hours The bowels tend to act 2–3 hours after food and often at night The changes in the stools (Strauss 1921) are an early feature Fairley and Kilner (1931) have found that in both sprue and gastro-colic fistula there is usually excess of fat in the stools and that it is well split In our case this was so before operation, but afterwards the stools returned to normal Various other authors (Castle et al 1930 Strauss 1921, Fairley 1930) have recognised the similarity between the findings in sprue and in gastro-colic fistula, and have noted a low blood-calcium and anæmia usually megalocytic, in both, but in gastro-colic fistula there is usually a high gastric acidity while hypochlorhydria is usual in sprue Our patient had a moderate hypochromic anæmia with no abnormal cells, this disappeared after operation without any iron other than in the food, gastric analysis showed hyperchlorhydria.

The importance of radiographic examination was emphasised by Strauss (1921) who said that gastro-colic fistula may sometimes be discernible only by barium enema This was confirmed in our case, for the barium meal was indeterminate, whereas the enema left no room for doubt, and on the second admission a clear result was obtained by enema alone

We would call attention to the ease and convenience of the continuous infusion of dextrose in fairly large amounts, together with insulin injections, as means of securing a satisfactory blood-sugar level with complete absence of ketosis The solution used was not normal saline solution with added dextrose, which would have tended to raise the salt content of the body unduly, but normal saline mixed with either 5 or 10% dextrose in water so as to form an isotonic solution

Our thanks are due to Dr Greenfield and his staff for the biochemical estimations

GASTRO-COLIC FISTULA COMPLICATING DIABETES MELLITUS

Ian M Anderson, M B GLASG , M R C P

Philip Hamill, M D CAMB , D SC LOND , F R C P

Robert Galloway, M B EDIN , F R C S E

(From an E M S Hospital)

Cases of gastro-colic fistula are not often reported Verbrugge (1925) collected 202 cases from the literature, Poynton and Macgregor (1930) collected 250 cases and reported 1 case Fairley and Kilner (1931) reported 3 cases, Mindline and Rosenheim (1935) a case and Bennett and Hardwick (1940) reported another The case reported here occurred in a diabetic, causing serious difficulties, and it illustrates a technique for the management of a diabetic patient in preparation for a serious abdominal operation and in after-treatment

CASE-HISTORY

A male civil servant, aged 52, was admitted to hospital on March 20, 1940, in diabetic coma He was semi comatose, breathing deeply, in severe ketosis and with a blood sugar of 0 46 mg per 100 c cm For 6 years prior to admission he had been a known diabetic and had been fairly easy to stabilise, 18 months before admission he had undergone a gastro enterostomy for a gastric ulcer , thereafter he had been well until a month before admission, when one evening after dinner he felt a sudden severe abdominal pain which continued until the next day , it left him with diarrhœa which persisted with occasional exacerbations up to the time of admission Owing to his abdominal discomfort and liability to diarrhœa he had become erratic in his diet and at times had had severe hypoglycæmic attacks Before the pain and diarrhœa began he had been stable on 20 units of zinc protamine insulin and 20 units of ordinary insulin daily, but since then the dosage had had to be greatly reduced , indeed, for the 2 days before admission he had had no insulin at all

In hospital there was a satisfactory response to insulin, dextrose and intravenous saline, and after a week he was receiving a 1400 calorie diet and in 3 weeks a 2100 calorie diet with three doses of 10 units of ordinary insulin daily On this diet his morning blood sugar was high, so his evening dose of insulin was increased to 20 units He then developed a severe nocturnal hypoglycæmic attack At the same time the diarrhœa increased and he lost weight The diarrhœa now became persistent, especially at night, and he had nocturnal hypoglycæmic attacks in which he sweated profusely and became extremely violent and disoriented On May 10 the insulin had had to be reduced to 5, 10 and 5 units It was clear that there was a relation between the severity of the diarrhœa and of the hypoglycæmia , presumably owing to failure to absorb carbohydrate The stools were greyish, with a fatty sheen suggesting the presence of fatty acid crystals On the history and these observations a diagnosis of gastro colic fistula was made with some confidence

Pathological and radiological examinations —Blood red cells 4,700,000 , Hb 75% , white cells 11,600 , no abnormal cells Serum calcium 8 8 mg , plasma phosphorus 2 8 mg , blood chloride 420 mg per 100 c cm Fractional test meal some increase in free and total hydrochloric acid Urinary diastase index 10 Stools total fat 59 3% of dried fæces, free fatty acid 23 9%, neutral fat 9 1%, soaps 26 3%

Dr E E Holdsworth reported the presence of a gastro colic fistula after a barium enema, the results of a barium meal being inconclusive

Preoperative treatment —Since the patient appeared to be somewhat dehydrated and no reliance could be placed on his power of absorbing carbohydrate by mouth, it was decided to administer 150 g of dextrose daily intravenously by slow drip, and to cover it with appropriate amounts of insulin At 10 P M on May 11 infusion was begun, the solution consisting of three parts of 5% dextrose solution and one part of normal saline , the rate of flow was 30 drops per min , and 5 units of insulin was injected into the lumen of the tube near the cannula every 2 hrs On the 13th the blood sugar was 0 15 mg at 11 A M The infusion was continued until 1 45 P M and the operation was begun at 2 30 P M Until that morning fluids were allowed freely by mouth in order to wash the stomach and intestine The patient's general condition immediately prior to oper

LONDON SATURDAY, OCTOBER 18, 1941

HOSPITALS FIRST

On Thursday of last week, in reply to a question in e House of Commons (see p 466), the Minister of ealth outlined the Government policy on the spital service after the war It is the objective of e Government, he said, to ensure that appropriate eatment shall be readily available to every person need of it This task will be laid on the major local thorities, whose duty it will be to secure a comehensive service by placing on a more regular footing eir existing partnership with the voluntary hospitals ut the design of the service is to be based on areas rger than counties and county boroughs, in order to clude in each a teaching hospital or other such centre which the more highly specialised services can be rovided Patients will be expected to make a easonable payment, whether by contributory schemes r otherwise, towards the cost of their treatment, the emainder being borne by the local authority or the oluntary hospital with the assistance of an Exchequer ontribution Teaching hospitals are to have inreased educational grants Such in broad outline is o be the sequel to the Emergency Hospital Scheme vhich came into being just two years ago It will not urprise those who have read the PEP report of December, 1937 ("The hospital problem is essentially egional   "), or have followed attentively the levoted labours of the Nuffield Provincial Hospitals Trust, with Sir Farquhar Buzzard as adviser, vhich have familiarised the country with a scheme of ospital reorganisation based on regional units Mr Ernest Brown in announcing his project for an mmediate survey of hospitals in Greater London cknowledges the valuable preliminary work done by he trust outside the metropolis He spoke of three tages in orderly progress consultation between all oncerned, which has already taken place , then the urvey , and afterwards the working out of the cheme—" of course,' he added, " with the approval f the Ministry " But he did not specify who is to ontrol the new regionalised hospital scheme—no loubt the right sort of independent corporation will be ound when the time comes—and he flatly declined o consider a general national health service or the uture of the medical profession as a whole , " that s," he said, " of course a wider question, and the ospital service must be considered first "

There are several reasons why the course of postvar hospital policy may be smoother than could have een foretold two years ago The state, as Mr E A Bedwell reminds us,[1] has now undertaken to eplace the damage done to parent hospitals by airaids, and the satellite hutments of 1939–41 are more attractive than those of 1914–18 with the result that patients like them " Some recent voluntary ospitals have cost £1000 or more a bed, but a 40-bed utment can be provided for £70 a bed One worldamous British hospital spent its first thirty years happily in the hutments of an even earlier war-period Mr Bedwell, reviewing the ground covered by the PEP report, speaks of the " silent revolution " in the hospital service effected by the Local Government Act of 1929 Under its de-rating clauses the million sterling grant from the Exchequer to voluntary hospitals (promised in 1924 and later repudiated) was more than handed over to the county councils to help them meet their dual obligation to provide hospital beds for all, and in so doing to consult the voluntary authorities Since then the hospital wagon has been drawn by a team which begins to look like a span Following London's admirable example, under the tutelage of Sir Frederick Menzies, local authorities all over the country are increasing their payments to voluntary hospitals for services rendered, under a wide variety of agreements , in the darkening valley their paths have drawn closer during the last two years The ideal area for hospital administration is also the ideal one for all sorts of public-health work and presumably for other large scale public activities That conviction, stated in these columns[2] when the Ministry of Health began to intervene, has only been strengthened by what has happened since But it may well be true, as Mr Bedwell suggests, that local authorities might be more easily reconciled to the surrender of their hospital control to a regional authority if they could retain their general care of the public health, for which a personal knowledge of the needs of the people and of their manner of living is essential At all events Hospitals First is the watchword, and we may be well content that the Government has committed itself to consultation, survey, preparation and settlement of a comprehensive scheme

LYSOZYME

In spite of the successes of the sulphonamides and acridines, and lately of penicillin, the demand for local antiseptics is not yet satisfied For some years the Russians have been investigating the possibilities of lysozyme Fleming,[3] its discoverer, gave this name to a class of enzymes possessing the power of dissolving a variety of micro-organisms These enzymes are almost universally distributed in animal tissues and body fluids They are found particularly in saliva, serum and tears, and, of the solid tissues, cartilage, but curiously enough they are absent from the cerebrospinal fluid High concentrations are found in white of egg Pure lysozyme was isolated by Roberts[4] and crystallised by Abraham and Robinson[5], it is a readily diffusible protein of low molecular weight which is rather more soluble in fats and oils than in saline and water Fleming clearly established that its physical properties were those of an enzyme It is not, for instance, used up in the course of bacteriolysis , it operates on bacteria over a narrow range of pH in the neighbourhood of neutrality, and it is inactivated in neutral or alkaline solution by moderate heat The substrate of lysozyme (the substance on which it acts) was thought by Hallauer[6] to be a glyco-protein, while Meyer and his colleagues[7] showed that reducing sugars were split off from the bacterial substrate during the course of digestion

A CASE OF POLYRADICULONEURITIS

WALLACE BRIGDEN, M B CAMB
LATELY HOUSE-PHYSICIAN AT SUTTON EMERGENCY HOSPITAL

THE case of polyradiculoneuritis described here made an unusually rapid recovery The disease appeared to be intermediate in type between the acute febrile form of Holmes and the Guillain-Barré syndrome as exemplified in the East Anglian epidemic described by Stuart Barber [1]

A previously healthy, well nourished man, aged 30 A fortnight before his first nervous symptoms he had a sore throat which he believes was unaccompanied by fever, from this he recovered in a few days Weakness and pain in the calf muscles, followed rapidly by numbness and weakness in the arms, heralded the paralytic stage Walking became impossible 3 days later He was then admitted to hospital and was found to have reduced power in both arms, the left being more affected than the right With the exception of the right triceps jerk all tendon reflexes were absent Thoracic muscles were normal, but the superficial abdominal reflexes were absent Both legs were in flaccid paralysis with all tendon reflexes absent, but the plantar reflexes were extensor His calf muscles were tender There was no proprioception from great toe movement, and some loss of epicritic sensation over a small area on the lateral aspects of both ankles, otherwise sensation was unimpaired There was persistent tachycardia and slight enlargement of the heart The cerebrospinal fluid was under pressure, and showed considerable rise in protein and no increase in cells The Wassermann reaction was negative During the next 3 days the facial muscles and recti abdominis, except in the right upper quadrant, became completely paralysed and speech was slurred, and on the fourth day it was noted that the left lower intercostals were involved Blood sedimentation rate 73 mm in 1 hour White cells 12,200 (polymorphs 77%, lymphocytes 18%) This marked the maximum extent of the paralytic process, which remained stationary for a further week, at the end of which the B S R had improved to 56 mm in 1 hour, and white count to 11,200 (polymorphs 69%, lymphocytes 30%) From this time the facial and intercostal muscles regained normal power in about a fortnight, while there was a general improvement in muscle tone, for some days stroking the sole produced a flexor response of the whole limb with extended toes During this recovery phase the B S R progressively fell, by the end of the fourth week reaching only 12 mm in 1 hour, the white blood cells were now 6000 (polymorphs 64%, lymphocytes 33%) In the next few days the abdominal muscles regained their power, the hamstrings and recti femora became almost normal, and proprioception returned Tachycardia subsided during the fifth week Seven weeks after admission he was able to stand and no signs of abnormality in the nervous system other than an indefinite plantar response on the left side were obtainable Normal walking soon followed B S R fell to within normal limits, but there was a slight unexplained rise in leucocytes

Intramuscular injections of 10,000 units of vitamin B_1 were administered daily for 10 days, and a third of this dose for a further 10 days No indications of vitamin deficiency existed before his illness, and it is doubtful whether this treatment helped in his rapid recovery Physiotherapy was given to the limbs for 2 weeks before he began to walk

In this patient the pathological process spread from the motor roots and anterior-horn region to involve the upper motor neurone, and in view of the slight sensory impairment other tracts were possibly also affected The rapidity of recovery suggests that the condition was due to no more than an inflammatory œdema or the diffusion of a locally produced toxin The raised B S R and leucocytosis favour the infective theories of its origi but differ from the findings in Stuart Barber's cases resemblance was found on examination of the C S F In other cases reported the B S R was either normal o not investigated This man responded well to th unknown noxious agent, this probably produces a generalised metabolic disturbance of which paresis ma be only one aspect The intensity of the patient response may have been related to the rapidity and completeness of his recovery.

I am indebted to Dr Louis Minski for permission to repo the case

---

[1] *Lancet*, 1940, 2, 548 The differential diagnosis, ætiology and pathology of the disease are discussed in Barber's paper

Reviews of Books

Doctor and Difficult Child

WILLIAM MOODIE, M D St And, F R C P, D P M medical director, London Child Guidance Clinic and Training Centre London Humphrey Milford, Oxford University Press Pp 214 8*s* 6*d*

THE Commonwealth Fund of America is to be congratulated on this publication, in these days of shortage and "ersatz" it is a joy to get hold of a book so beautifully bound and printed Nor are the contents less pleasing, from his vantage as a pioneer of child psychiatry in this country, Dr Moodie has surveyed the whole range of problems which a child is likely to present to its harassed parents or teachers The book could be used as a manual of practical advice, not only to doctors, but to anyone who deals with children and their problems The author has all the good Scots belief in hard work and sound education, and the danger is that the two may suppose that it is all as easy as it looks "The education of neurotic or so-called 'nervous children' needs special care" says Dr Moodie "They require to be kept interested and encouraged to make an effort They must not, on any account, be driven Education has special value for them because it utilises the mental energy which is behind their nervous symptoms, and at the same time it gives them things to think about and so directs their thoughts from themselves and their fears" But having led the horse to water, how to make him drink? Mechanisms are not dealt with in detail, and the book should be read less as a textbook in child psychiatry than as a pleasant account of the way in which many problems in childhood can be sensibly approached and satisfactorily treated

Practical Biochemistry for Students of Medicine

(4th ed) A T CAMERON, D Sc Edin, F R S C, and FRANK D WHITE, Ph D Edin London J and A Churchill Pp 246 9*s* 6*d*

FIVE years separate the new edition of this approved Manitoba manual from the previous one, but the authors have made but few innovations, preferring, as they state, to keep the old tested methods as far as possible However, an account of the micro Kjeldahl estimation has been introduced, and also the estimation of ascorbic acid and Fearon's test for citrulline A possible weakness of this book is the rather scanty section on the blood pigments, while for the estimation of phosphate in urine the use of cochineal as internal indicator might be preferred to the external use of ferrocyanide Strong points are the excellent section on alkali reserve, the introduction to liver function tests vitamins and hormones, and the instructions for the handling and standardisation of quantitative apparatus

Catechism Series Surgery

(5th ed) Edinburgh E and S Livingstone Pp 7 In two parts, each 1*s* 6*d*

Part 1 deals with the general aspects of surgery such as infections, hæmorrhage, shock and gangrene, and diseases of bone Part 2 embraces fractures, dislocations and diseases of joints It is surprising what a wealth of information is contained in these necessarily compressed accounts, and for what they are—unashamedly examination cram-books—these slight volumes are commendably up to date and informative The introduction of X-ray photographs is a useful new feature, most of these have reproduced sufficiently well to be of value t the student but some (notably Paget's disease of th tibia and the benign giant-cell tumour) should b strengthened or replaced in the next edition

THE LANCET

LONDON SATURDAY, OCTOBER 18, 1941

HOSPITALS FIRST

ON Thursday of last week, in reply to a question in House of Commons (see p 466), the Minister of alth outlined the Government policy on the spital service after the war It is the objective of Government, he said, to ensure that appropriate atment shall be readily available to every person need of it This task will be laid on the major local thorities, whose duty it will be to secure a comehensive service by placing on a more regular footing eir existing partnership with the voluntary hospitals it the design of the service is to be based on areas rger than counties and county boroughs, in order to clude in each a teaching hospital or other such centre which the more highly specialised services can be rovided Patients will be expected to make a asonable payment, whether by contributory schemes r otherwise, towards the cost of their treatment, the emainder being borne by the local authority or the oluntary hospital with the assistance of an Exchequer contribution Teaching hospitals are to have increased educational grants Such in broad outline is o be the sequel to the Emergency Hospital Scheme which came into being just two years ago It will not urprise those who have read the PEP report of December, 1937 ("The hospital problem is essentially egional "), or have followed attentively the evoted labours of the Nuffield Provincial Hospitals Trust, with Sir **Farquhar Buzzard** as adviser, which have familiarised the country with a scheme of ospital reorganisation based on regional units Mr **Ernest Brown** in announcing his project for an immediate survey of hospitals in Greater London cknowledges the valuable preliminary work done by he trust outside the metropolis He spoke of three tages in orderly progress consultation between all concerned, which has already taken place, then the survey, and afterwards the working out of the scheme—" of course," he added, " with the approval f the Ministry " But he did not specify who is to control the new regionalised hospital scheme—no oubt the right sort of independent corporation will be ound when the time comes—and he flatly declined to consider a general national health service or the uture of the medical profession as a whole, " that s," he said, " of course a wider question, and the hospital service must be considered first "

There are several reasons why the course of post-war hospital policy may be smoother than could have been foretold two years ago The state, as Mr C E A **Bedwell** reminds us,[1] has now undertaken to eplace the damage done to parent hospitals by air-aids, and the satellite hutments of 1939–41 are more attractive than those of 1914–18 with the result that " patients like them " Some recent voluntary hospitals have cost £1000 or more a bed, but a 40-bed hutment can be provided for £70 a bed One world-amous British hospital spent its first thirty years happily in the hutments of an even earlier war-period Mr **Bedwell**, reviewing the ground covered by the PEP report, speaks of the " silent revolution " in the hospital service effected by the Local Government Act of 1929 Under its de-rating clauses the million sterling grant from the Exchequer to voluntary hospitals (promised in 1924 and later repudiated) was more than handed over to the county councils to help them meet their dual obligation to provide hospital beds for all, and in so doing to consult the voluntary authorities Since then the hospital wagon has been drawn by a team which begins to look like a span Following London's admirable example, under the tutelage of Sir **Frederick Menzies**, local authorities all over the country are increasing their payments to voluntary hospitals for services rendered, under a wide variety of agreements, in the darkening valley their paths have drawn closer during the last two years The ideal area for hospital administration is also the ideal one for all sorts of public-health work and presumably for other large-scale public activities That conviction, stated in these columns [2] when the Ministry of Health began to intervene, has only been strengthened by what has happened since But it may well be true, as Mr **Bedwell** suggests, that local authorities might be more easily reconciled to the surrender of their hospital control to a regional authority if they could retain their general care of the public health, for which a personal knowledge of the needs of the people and of their manner of living is essential At all events Hospitals First is the watchword, and we may be well content that the Government has committed itself to consultation, survey, preparation and settlement of a comprehensive scheme

LYSOZYME

IN spite of the successes of the sulphonamides and acridines, and lately of penicillin, the demand for local antiseptics is not yet satisfied For some years the Russians have been investigating the possibilities of lysozyme **Fleming**,[3] its discoverer, gave this name to a class of enzymes possessing the power of dissolving a variety of micro-organisms These enzymes are almost universally distributed in animal tissues and body fluids They are found particularly in saliva, serum and tears, and, of the solid tissues, cartilage, but curiously enough they are absent from the cerebrospinal fluid High concentrations are found in white of egg Pure lysozyme was isolated by **Roberts**[4] and crystallised by **Abraham** and **Robinson**[5], it is a readily diffusible protein of low molecular weight which is rather more soluble in fats and oils than in saline and water **Fleming** clearly established that its physical properties were those of an enzyme It is not, for instance, used up in the course of bacteriolysis, it operates on bacteria over a narrow range of pH in the neighbourhood of neutrality, and it is inactivated in neutral or alkaline solution by moderate heat The substrate of lysozyme (the substance on which it acts) was thought by **Hallauer**[6] to be a glyco-protein, while **Meyer** and his colleagues[7] showed that reducing sugars were split off from the bacterial substrate during the course of digestion

[6] *Zbl Bakt* 1929 119, 240

[7] *J biol Chem* 1936, 113, 303

These facts were reconciled by EPSTEIN and CHAIN,[8] who showed that lysozyme, like "spreading factor," is a carbohydrase, and that lysis of bacteria takes place when the products of hydrolysis, like the purified substrate, are soluble in water It is probable that the substrate has protein attachments in the bacterial envelope, and that lysis in addition to antisepsis—an important distinction first made by EPSTEIN and CHAIN—occurs only when the conditions of digestion are such that the bacterial proteins dissolve in the digestion fluid Thus, as NAKAMURA[9] first observed, a mere adjustment of pH may bring about the "flash lysis" of bacteria which are structurally unaffected by the enzyme

There are serological differences between samples of lysozyme from different sources,[10] but all alike digest the purified substrate in vitro The test organism since universally used for examining the action of lysozyme was isolated by FLEMING from nasal mucus and named by him *Micrococcus lysodeikticus* He found that three-quarters of more than 100 airborne microbes studied, including bacilli, yeasts and moulds as well as cocci, were susceptible to lysozyme, but some classes of bacteria, notably the coli-typhoid group, are totally resistant to its action A striking fact is that *Brucella abortus* and *Bacillus pseudotuberculosis rodentium* are moderately susceptible these, FLEMING writes, "are culturally and serologically identical with *Micrococcus melitensis* and *B pestis* respectively, both of which are very pathogenic for man, and for which there is apparently no lysozyme in the human secretions It may be that it is in this sensitiveness to a human lysozyme that the difference between these microbes lies" Unfortunately it is chiefly, though not entirely, on the non-pathogenic organisms that lysozyme acts, the determining factor, EPSTEIN and CHAIN point out, is whether or no the enzyme substrate is present in the bacteria *B anthracis*, for instance, is destroyed though not dissolved by lysozyme Many organisms may in fact be non-pathogenic because of their susceptibility to lysozyme Moreover, FLEMING found that by exposure to lysozyme bacteria may acquire, and maintain during cultivation, a resistance to its action Thus RIDLEY observed that lysozyme-resistant survivors from an originally innocuous strain of staphylococci had acquired, with their resistance, the power of producing keratitis when injected into the cornea of rabbits

There are, then, serious limitations to the powers of lysozyme as an antiseptic, and there is still another difficulty to be faced if lysozyme is to be given by injection or applied to raw vascular surfaces This is that in such circumstances lysozyme will act as an antigen, and the recipient may find himself sensitised to the foodstuffs which contain the enzyme So far egg-white has been the only practicable source of lysozyme in quantity Treatment with this "foreign" lysozyme might sensitise the patient to eggs, though not to other animal foodstuffs since their lysozyme is serologically different, and the antigenic effect would not be destroyed by ordinary cooking This objection, however, will not apply to the application of lysozyme to the eye or unbroken serous surfaces

For the last ten years YERMOLJEVA, BUJANSKAYA their colleagues in Russia have been examining possibility of using lysozyme in surgery In the s review[11] they published in 1938, before purified l zyme was available for their use, they reported encouraging results in the treatment of co ulcers, in the general surgery of the eye and elsewhere How far these applications can usefully be extended remains to be seen

HEALTH AND THE JOB

DOCTORS are usually fair-minded people but if their outlook has a bias it may be said that it points naturally and justifiably, like the needle of a compass towards the interests of their patients, for when someone comes for help and advice it would only be a churlish fellow who did not respond to the compliment and do his best Not all doctors, however realise the weight that medical certificates carry nor how great an influence the medical profession in the aggregate can exert on the war effort Workpeople know that doctors are ready to help them in their troubles and they are accustomed to seek medical certificates to support their physical and psychological objections to doing night work, an unpleasant job, or working in a particular factory controlled by the Essential Work Order Many such objections and applications are genuine and the medical certificates are rightly issued after adequate deliberation by the medical men If however the doctor states, in good faith but without first-hand knowledge, that the factory conditions or processes are detrimental to the worker's health, his certificate goes beyond his experience In the Sheffield district, for example, the process of grinding has a bad name because the dust from the sandstones which were used in the past gave rise to grinders' rot or silicosis Nowadays nearly all sandstones have been replaced by artificial abrasive wheels made of non-siliceous materials and grinders on the whole are no longer exposed to the risk of silicosis Other processes go by the name of grinding such as "precision grinding" in the manufacture of machine tools The grinding is often done by a diamond point from which little or no dust arises, and in all cases the work is either done wet or under exhaust ventilation But in Sheffield grinding is still grinding (in the same way as pigs is pigs whether guinea or otherwise) and therefore dangerous to health—and this folk-lore is apt to be reflected in doctors' certificates Such lack of knowledge or discrimination, if it is not checked, can have a deleterious influence on the output of essential war material On another page a letter from a works manager illustrates this point

When a doctor is confronted by a worker who asks for a medical certificate stating that his work is endangering his health, he would do well to bear in mind that such a certificate cannot justifiably be given unless he knows both the worker's state of health and the conditions of his work The doctor can take his choice between going to look at the job the worker has been doing, getting in touch with the works medical officer (if there is one) and discussing the case with him, or consulting one of H M medical inspectors of factories who are stationed in London, Birmingham Bristol, Sheffield, Leeds, Manchester and Glasgow, d are always ready to advise on occupational health sks in general or on the processes of a particular ctory

EMPORARY IMMUNITY AGAINST INFLUENZA

WHILE we await the development of a trustworthy ethod of active immunisation against influenza, the emporary protection conferred by immune sera is not ecessarily to be despised Such evidence as there s suggests that the prospects of achieving a local passive immunity are hopeful SMORODINTSEFF[1] reported promising results from the inhalation of finely dispersed immune horse-serum, but full details are not available TAYLOR[2] has lately described the results of experimental studies on influenza A virus infection of mice A single dose of immune ferret serum administered intranasally to mice protected them against virus introduced by the same route 24 hours later, even after 48 hours some protection was given Serum applied intranasally after virus infection achieved much less, but there was a definite effect if the interval between infection and administration of serum was not greater than 6 hours Intranasal serum was in all experiments far more effective than intraperitoneal, apparently because it achieved a high antibody concentration at the spot where it was most needed There must be some danger from producing sensitisation by administering foreign sera intranasally to human beings, but convalescent human sera should be available quite early in an epidemic and methods of quickly estimating the potency of these are known Even temporary protection of key persons would often be worth while For instance, as often happens, if father and the children are all down with the 'flu and mother is looking after them, much would be gained if she could be protected during the difficult period by sniffing antibody once or twice daily But further work is needed to establish that TAYLOR's findings can be applied to war, and it has yet to be decided whether the effect could be best achieved by installation of liquid or by using snuff or a fine spray A great attraction of the sniffing technique is that it could be applied not only to influenza A—the variety of influenza most troublesome in recent years—but perhaps to other virus infections also It may be that pandemic influenza is due to neither of the known viruses, A and B We may one day be faced with a devastating scourge such as that of 1918–19, with little hope that laboratory studies can provide a remedy in time Prophylactic application of convalescent serum to the nasal passages might then prove a godsend, capable of being put into effect even by those isolated from centrally organised help

THE new crop of war-blinded are reaching St Dunstan's Captain Sir Ian Fraser, chairman of the executive council, finds them more serious minded than their forerunners of the last generation They are quick learners in walking about wards and classrooms, and many have already passed the exacting tests in braille reading and typewriting expected of them, and have begun to share in the indoor and outdoor games and recreations open to them, including cards, dominoes, tug-of-war, rowing, tandem cycling (presumably with a seeing partner), acting, music and dancing "Recovery of sight," Sir Ian writes in the twenty-sixth annual report, "is impossible for many but recovery from blindness is the rule"

Annotations

SOURCES OF VITAMIN C

ONE of the most striking changes in our diet since war began has been the fall in the consumption of fruits Few raspberries, strawberries and blackcurrants have been obtainable this summer outside the districts where they are grown, and the large supplies of fruit which could normally be expected for winter and spring—oranges, lemons, grapefruit, bananas and the wide variety of canned fruits—have been greatly restricted[1] These fruits are mainly of dietetic importance for their vitamin-C content Holmes, Pigott and Tripp[2] point out that, on an average, 110 ml of orange, grapefruit or lemon juice will supply the 50 mg of ascorbic acid which the adult probably requires daily The importance of these citrus fruits in normal times lies not only in their high antiscorbutic value but also in their relatively low cost as sources of vitamin C,[3] and alternative cheap sources of the vitamin are therefore needed Andross[4] has collected some useful information on the vitamin-C value of wild fruits, and has tested jams, juices and puree made from wild rose hips, elderberries, wild raspberries, cranberries, bilberries and crab apples Of these fruits wild rose hips alone seem to be worthy of practical consideration as antiscorbutics Pezold[5] in Germany quotes values ranging from 500 to 1100 mg of ascorbic acid per 100 g of wild rose fruit He also discusses the effect of various methods of presenting hips in an edible form and urges the importance of picking the fruit before they are over-ripe when they lose something like half of their vitamin-C content He considers that during the winter months responsibility for vitamin-C intake must lie largely with the jam manufacturer, for he found that jam is one of the most effective ways of preserving the hips He also strongly recommends hip wine, but this might be an impractical suggestion for this country where the commercial preparation of fruit wines is not so common as in Germany Here the housewife has been rediscovering the tastiness of hip marmalade and hip jelly, and hips are being collected on a large scale by women's institutes, schools, boy scouts and girl guides It is hoped to convert some 500 tons into syrup The picking organisations are to receive 2s per 14 lb for the fruit, so that it should be possible to sell the syrup at a reasonable price Among our cultivated fruits we have a rich source of vitamin C in blackcurrants, and the Ministries of Food and Health have reserved a significant proportion of this year's crop in the form of puree and juice for young children But the supply of vitamin C for older children and for adults too must be considered Olliver[6] reports that in the spring of this year, cooked green vegetables provided almost all the vitamin C in the diet of test subjects, and that one 4 oz helping of freshly cooked green vegetables could supply the total daily requirement of the vitamin Root vegetables, such as potatoes, may be valuable antiscorbutics when freshly harvested but are poor sources of the vitamin in the spring owing to loss on storage The consumption of green vegetables in the late winter and spring is obviously to be encouraged, provided the material is properly handled Olliver's experimental work emphasises the need for the careful cooking of vegetables and shows that about half the vitamin C is destroyed after the vegetables have been kept hot for only 40 minutes These results, together with the recent summary by the Medical Research Council[7] of the best methods of preparing green vegetables for the table, should be impressed on housewives and caterers, and especially those who are responsible for feeding large numbers of children

PELLAGRA IN SPAIN

THE unhappy Spanish war led to malnutrition of which the extent can be inferred from the numerous clinical papers on vitamin deficiency in Iberian journals Thus in the second number of the new *Acta Española Neurologica y Psiquiatrica there are three articles based on only* too rich an experience B Llopis has studied 118 cases of psychosis due to pellagra, from the initial to the final stages, he reports endogenous as well as organic syndromes, and has observed four stages in the disorder—neurasthenia, apathy, oneiroid confusion and, finally, profound disturbance of consciousness, which are respectively akin in his judgment to mental fatigue, going to sleep, light sleep and deep sleep The psychological content of these syndromes is derived from organic disturbances of sensation, which are localised, and the translation of which into hallucinations can be clearly traced in the patients, facilitated as it appears to be by the clouding of their consciousness Llopis devotes the greater part of his paper to a review of the significance of this for psychopathology From Madrid, J Marquez Blasco and M Peraita contribute two papers on the capillaries and the skin temperature in this disorder During the autumn and winter of 1937, they state, a great part of the civil population of Madrid showed a syndrome, essentially of pellagrous nature, characterised chiefly by paræsthesiæ, a smaller group, more gravely affected, showed the "rich and singular symptomatology" of a pellagra syndrome in which burning pain, similar to causalgia, was prominent The authors decided therefore to see what part the capillary system played in these causalgia-like phenomena, *they used the clinical material* of Llopis, and of Jimenez Garcia, as well as Peraita's own cases—56 in all, with neurological disturbances in all but 6 Absolutely normal capillaroscopic findings were never found, but 54% of the cases were in the main normal in this respect, and in 18% the picture was quite abnormal The capillary changes increased as the illness went on, and were related to neurovegetative disturbances There did not appear to be any connexion between the type of capillary anomalies and the presence or absence of cutaneous and mental symptoms, They found, in 40 subjects whose cutaneous temperature was measured, that there were in the extremities many departures from the normal (the readings being lower, as was to be expected from the frequency with which these patients complained of coldness in the extremities) whereas in proximal zones, such as the forehead, normal readings were obtained The vasomotor control was investigated in 6 of the cases and in 5 of them judged abnormal, the response to immersion of the arm in warm water being either delayed or incomplete

CYCLICAL CHANGES IN HUMAN ENDOMETRIUM

THE unique activities of the glandular cells of the endometrium during the menstrual cycle have been further investigated in Dublin by O E Aykroyd and J Bronte Gatenby[1] Taking advantage of recent advances in *histological technique they have been able to show a* remarkable series of changes in the Golgi apparatus and paraplasmic inclusions, corresponding to different phases in the cycle, which they divide into the proliferative, progravid, menstrual and postmenstrual periods At menstruation the Golgi apparatus suddenly disperses while much of the cell contents is thrown into the lumen But the Golgi apparatus of the basalis portion of the endometrium, which is not shed, undergoes a similar change During recovery the fragments of Golgi apparatus are gathered into a transverse line parallel with the free margin of the cell, producing thus a palisade effect when a row of cells is viewed, though there is no evidence of any intercellular connexion between adjacent pieces of the apparatus During the proliferative phase (lasting from the fifth or sixth day to the fourteenth day after menstruation) the Golgi apparatus reforms into the usual net-like arrangement lying near the nucleus and remains thus for the remainder of the cycle In this proliferative phase no sudanophil fat is found within the cells, but droplets appear on a small scale early in the progravid phase (fifteenth to twenty eighth day) and thereafter increase This fat becomes greatly exaggerated if pregnancy supervenes, in menstruation it is shed into the lumen These changes in the Golgi apparatus are interpreted by Aykroyd and Gatenby as representing the preparation of the apparatus for the active production of a solid, probably proteid, secretion related to early pregnancy This secretion, appearing in the form of cytoplasmic droplets stainable with Heidenhain's iron hæmatoxylin, is increased in the cells in early pregnancy and is a feature of diagnostic help in the histological examination of curettings from a suspected case of interrupted pregnancy The physiological significance of this secretion seems to be unknown It would be useful to know if it is also present in association with other conditions giving a positive Aschheim Zondek test

CHEMOTHERAPY IN TUBERCULOSIS

SUBSTANCES which have been administered to the long suffering patient in the vain hope that they would destroy the tubercle bacillus without first destroying him are enumerated by Calmette as follows salts of calcium, gold, silver, bismuth, copper, and the rare earths of the ceric group, formic aldehyde, benzyl alcohol, xylol and the creosote series, iodine and its compounds, dyestuffs, and the fatty acids of chaulmoogra and cod-liver oil Even this list is by no means complete Gold has had the best press, and still has its disciples—and martyrs During the last five years a new school has arisen, as was inevitable, to try out the sulphonamides, and a large number of papers has been published recording experiences of administrations to patients and experiments in vivo with laboratory animals and in vitro with various strains of tubercle bacillus on different culture media Lately Feldman and Hinshaw[1] in America have noted a definite modification and retardation of the expected course and character of experimental tuberculosis in guineapigs receiving sulphapyridine, though they encountered unpleasant results on the mucosa of the digestive tract Feldman and Karlson[2] also tested it on rabbits infected with avian tubercle bacilli, but with unsuccessful results Heise and Steenken[3] encountered similar disappointments with guineapigs, and noted that the growth of the tubercle bacilli was not entirely inhibited by sulphapyridine introduced into the culture media even in concentrations of 80 mg per 100 c cm Flippen Forrester and Fitz Hugh[4] confirmed these negative findings, and it looks as though another chapter of failures has been closed A variant of these chemotherapeutic experiments has been made by controlling the oxygen Saz and Bernheim[5] set out to find a substance which would inhibit extra oxygen intake, the drug known as 2 3 5 triiodobenzoate being *selected* With this compound in very low concentration inhibition of growth was obtained on culture media It is tolerated by rats and guineapigs, and man can take it by mouth without apparent ill effects—and absorb it from his gastro intestinal tract Apparently it can inhibit growth without destroying cells The difficulties of all this work are obvious Not only is the chemo pist faced with the task of damaging the bacilli out damaging tissue cells which is common to all of this kind, but he has to encounter two additional acles In the first place the histological tubercle is cular, and quite early in its development has a zone rotective collagenous fibres around it Secondly, the y envelope of the tubercle bacilli is a law unto itself n in a test-tube it is difficult to destroy, and attempts lo so in living tissues, with drugs of known potency apsule destruction such as sulphapyridine, have not n conspicuously successful A new method of roaching the problem has now been devised by mart and Smith,[6] with an ingenious technique for ivating the tubèrcle bacillus on the chorio allantoic mbrane of the chick embryo In this way they are e to obtain tubercles within 4–6 days of implantatión, l to make cytological studies of the reactions to the erent cultures used This method may enable the motherapist to obtain what he has long been wanting rapid picture of the tissue reaction to a drug in erculosis

SPONTANEOUS" RUPTURE OF THE SPLEEN

THERE have been about 20 reports in the last 20 years spontaneous rupture of the normal spleen, and though t all of them bear scrutiny there are a few careful cords under this self-contradictory title Rupture of e spleen is a known if rare complication of malaria d typhus fever and it is not unknown in typhoid or deed in almost any disease where the spleen is enlarged this country it is usually caused by trauma and the roplane and motor-car have done much to increase incidence Of more immediate interest are those stances of delayed rupture where a patient receives blow but after a short time appears normal and may en return to work only to collapse several hours or ys later with serious internal bleeding The cause delayed rupture is not certain but it is believed that the iginal splenic tear is quickly sealed by coagulation or nentum and that the bleeding starts again when is plug is dislodged Another possibility is that the iginal injury produces a subcapsular hæmatoma with bsequent pressure necrosis, softening of the pulp and osion of fresh and large vessels In spontaneous pture such delayed effects of trauma must be excluded d adequate histological examination of the spleen ust be made before the diagnosis can pass muster ius King's[7] case report of spontaneous rupture in ectious mononucleosis, which contains one of the few tailed descriptions of the pathological findings in that ease, is not in the accepted sense spontaneous since e spleen was greatly enlarged In Hamilton Bailey's[8] t of 11 recorded cases it is noted that in 4 no microopical examination of the spleen was made, and in 1 was said to be apparently normal Nor is it wise to ike all on a casual or even a categoric denial by the tient of a blow and Hamilton Bailey's view that the leen cannot be ruptured without the patient remember- the knock is certainly open to question Workers industry often receive blows which are capable of using grave injury but are quickly forgotten if they do t involve immediate incapacity for work The time tor is important and a case-record by Hohenwallner[9] ens the question of just how long a delayed rupture of e spleen may be delayed Hohenwallner's patient is struck on the chest on Sept 2 but after a short rest recovered and went on working until Jan 3 when he is found to have abdominal bleeding from an old tear the upper pole of the spleen That the injury received ur months previously caused the rupture and the later ness seems evident and the implications both to the practice of traumatic surgery and to the theory of spontaneous rupture are obvious It may be that sometimes neither trauma nor any known change in structure plays a part in the so called spontaneous rupture of the spleen but if the cause is unknown it is better to avoid euphemistic terms like "spontaneous" and say so plainly when we do not know.

AN APPOINTMENT IN SUSPENSE

THE Dudley town council has affirmed by 15 votes to 13 its decision to suspend its medical officer of health Dr W A McLennan, for the duration of the war Its sole reason is that, being obliged by law to register for military service, Dr McLennan registered as a conscientious objector in the manner prescribed by law There is no suggestion that he is incompetent on the contrary, his efficiency has been publicly acknowledged The Government, and indeed the Minister of Labour and National Service himself, long ago deprecated any victimisation of those whose conscience leads them to follow a course which the law expressly permits The borough is depriving itself of a key officer of recognised ability and experience at a moment when these qualifications are particularly important and when replacement must be made from a limited field and from relatively inexperienced applicants It can hardly be supposed that this aspect of the most profitable use of medical man-power can have escaped the attention of the Minister of Health It is understood, however, that he has hitherto found himself unable to convey to the town council of Dudley any suggestion that its decision should be reconsidered

UROLOGICAL COMPLICATIONS OF CERVICAL CARCINOMA

ALL gynæcological textbooks lay emphasis on urological complications as a cause of death in carcinoma of the cervix, but a thorough urological investigation is often omitted in such cases except when obvious symptoms focus the surgeon's attention on the urinary tract Anatomically, this tract is most vulnerable to carcinoma of the cervix in its lower reaches—in the bladder and the pelvic portions of the ureter, notably where they traverse the base of the broad ligament Lesions of the urethra, the abdominal part of the ureter, or the kidney are secondary findings caused either by advanced malignancy or by back pressure from ureteric obstruction Renal metastasis is rare and was seen only once by T F Todd[1] among over 1000 cases of carcinoma cervicis The incidence of involvement of the lower urinary tract can be judged from his statement that he saw bladder involvement in 110 cases at their first attendance, whereas the rectum, that other close neighbour of the cervix, was involved only once in all cases prior to treatment The growth first invades the muscle wall, causing circulatory changes in the mucosa, and next spreads forwards into the mucosa, finally ulcerating and producing a vesico-vaginal fistula Cystoscopy, and cystoscopy alone, can diagnose these bladder changes in their early stages The mucosa is at first congested and distorted, there is transverse ridging of the base of the bladder, with isolated hillock formation, and later bullous œdema and finally ulceration These last two phenomena place the patient in stage IV of the League of Nations classification The importance of this cystoscopic examination is that in 195 cases clinically assessed as stage III no less than 44 showed involvement of the bladder in Todd's series—a clinical error of 20% The prognosis in these cases is thus gravely affected by the urological investigation It is not, however, only as a diagnostic and prognostic procedure that cystoscopy is of value, but also in the urological complications of treatment These are twofold recurrent malignant disease in the bladder,

not differing in appearance from that of the untreated case and therefore self-evident on examination, and postradiation ulceration—quite a different entity In Todd's series postradiation ulceration was rare, he saw only 10 cases in 5 years, and of these only 4 proceeded to the stage of ulceration, the remaining 6 showing merely a telangiectatic atrophy of the vesical mucosa The ulcers were all situated above the interureteric bar, and had suspicious heaped-up edges and a surrounding zone of bullous œdema, the adjacent mucosa was blanched, with scattered telangiectatic spider-web patches, the ulcer was occupied by a slough Treatment is expectant, and in 3 of the 4 cases the ulcer healed spontaneously with a scarred bladder base The diagnosis of the radio-necrotic ulcer is made on the cystoscopic appearance and the absence of any definite malignant lesion For the malignant ulcer there is no treatment Todd divides ureteric complications into three groups those occurring in untreated cases, and those following surgical and radiation treatment In the first group he investigated 90 cases before treatment by retrograde or intravenous pyelography Two of these 90 were in stage I and had no urological complications, among 26 in stage II he found hydronephrosis in 3 Among 32 in stage III he found hydronephrosis in 5 and a functionless kidney in 3 and poor renal function in 1, and among 30 cases in grade IV 10 showed hydronephrosis and 9 a functionless kidney In many of these cases the blood-urea, investigated as a routine before treatment, was within normal limits In a follow-up of his cases with urological complications in the upper urinary tract, Todd found that the prognosis was particularly gloomy Post-radiation complications of the upper urinary tract are not uncommon in patients investigated months or years after treatment, and Todd places the figure as high as 50% in a small series that he investigated The lesion noted was some form of ureteric obstruction, but whether the cause was actual stenosis from growth or fibrosis he declined to decide

TROUBLE WITH TRIGONELLINE

THE assessment of nutritional status is gradually being placed on a quantitative basis Thanks largely to the work of Leslie Harris and his collaborators at Cambridge, methods have been evolved of estimating the level of nutrition in respect of certain water-soluble vitamins They found that people with recognisable vitamin deficiency—for example, with scurvy—excreted much less of the vitamin in the urine than did people on diets well provided with it[1] The "saturation" tests evolved by these investigators made it possible to determine the amount of (say) vitamin C which it was necessary to administer as "test doses" before the excess overflowed in the urine By comparison with subjects known to be receiving optimal amounts of the vitamin it became possible to determine with some degree of accuracy the deficit of the vitamin in subjects who were only mildly below standard and who had no obvious clinical manifestations of scurvy Such tests have since been used extensively for assessing[2] the nutritional level of vitamin C and, more recently,[3] of vitamin B_1 Since the discovery and identification of nicotinic acid as the pellagra-preventing vitamin many workers have elaborated methods for estimating it in the urine, in the hope of developing a saturation test for detecting its deficiency It is now possible to determine the amount of the vitamin excreted with some degree of accuracy, and several investigators have already found that the "resting" excretion—i e, in the absence of test dosing—is diminished in deficiency of this vitamin[4] It was recognised though, that test dosing would probably a better indication of deficiency than the simple mination of resting levels Some workers, for e suggest that there may be overlap in the excretions, so that normal subjects occasi excrete less nicotinic acid than subjects who deficient[5]

The question of test dosing is however complicated the fact that ingested nicotinic-acid is excreted in urine partly as such and partly as other conjugated degradation products, the most important of which trigonelline The excretion of trigonelline, which biologically inactive, is also affected by factors other nicotinic-acid intake, being especially increased substances rich in trigonelline such as legumes B provided the diet is free from trigonelline, it has be shown independently by workers both in America[5] a in Cambridge[6] that the resting excretion of trigone is diminished in deficiency, and this diminution may more considerable than that of the nicotinic acid it The Cambridge workers have also devised an accur method for estimating trigonelline, which previou has only been determined semi-quantitatively Th suggest that the saturation technique (in which the vitamin is given and the excretion of trigonelline measure provides a better measure of antipellagra status than th measurement of the resting level of excretion, the amount of trigonelline derived from the controlled diet will be insignificant compared with the much larger quantities produced from the test doses of the vitamin On the other hand, should it be impossible to arrange for the controlled diet and for the test dosing, the estimation of nicotinic acid in the urine is to be preferred to that of trigonelline, since nicotinic acid is derived from the vitamin alone, whereas trigonelline may be derived from biologically inactive substances in the diet It wi be of interest to see further results in this field, particularly since it has been suggested that nicotinic ac deficiency may play a part in the causation of Vincent angina and of some types of stomatitis as well as pellagra-like dermatitis

RADIUM THERAPY IN WAR-TIME

M LEDERMAN,
M B LOND , D M.R.E
RADIUM THERAPIST, ROYAL
CANCER HOSPITAL (FREE)

W V MAYNEORD,
D SC BIRM , F INST P
PHYSICIST TO THE HOSPITAL

AT the outbreak of war radium therapy was one of the w branches of medicine the practice of which seemed advisable, if not impossible, under the anticipated nditions of warfare Not only is radium very costly, that the loss of any large quantity would prove a rious financial problem to any hospital or doctor but the event of the destruction of radium-containing pparatus by bombing the scattering of the contained adium salt might render the site of disaster dangerous ntil the dispersed radium could be recovered Should ecovery not prove possible the scattered radium salt would retain its radio-active properties for centuries and onstitute a possible danger to workers undertaking learance of the site or erection of new buildings, or to uture inhabitants of the buildings

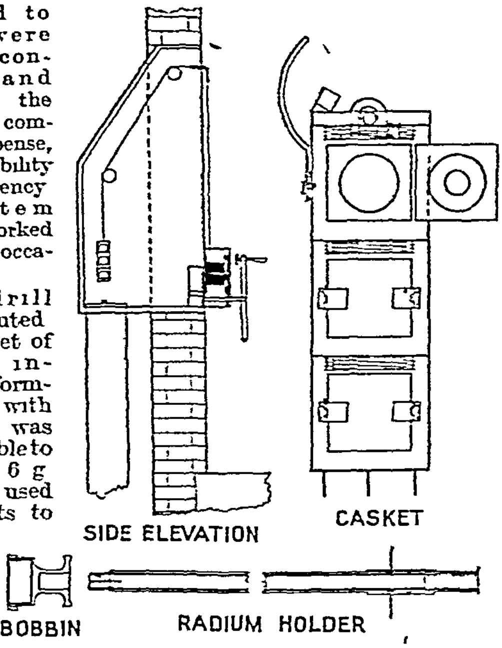
The scattered radium salt is harmful inasmuch as its entry in the form of radio-active dust into the body, by inhalation or ingestion, results in radium poisoning [1, 2] a condition which should not be confused with the effects of the therapeutic use of radium, wherein the body tissues are exposed to the radiations from radium and its products After entry into the body radium behaves in a manner comparable to lead, being carried in the blood-stream and either excreted, or deposited in the bones bone-marrow, liver, lungs and spleen. The rate of elimination is at first rapid but quickly diminishes with the passage of time. After a year any radium in the body is to all intents and purposes fixed The clinical phenomena associated with radium poisoning are chronic, and arise from the fixed radium which acts by producing an alpha-particle bombardment of the tissues in which it is deposited Usually no harmful effects are noticed until years after the entry of the radium into the system That the osseous and hæmopoietic systems suffer chiefly is shown by the occurrence of bone necrosis radiation osteitis, spontaneous fracture and osteosarcoma Changes in the blood are usually in the form of regenerative anæmia of the myeloblastic or pernicious type, in contrast to the anæmia secondary to excessive gamma radiation, which tends to be aplastic Colwell and Russ [2] say “It has been estimated that 10 microgrammes of radium distributed over the whole skeleton would be sufficient to produce a horrible death, years after it had been ingested So far as we can see, radium is thus the most deadly poison known , tetanus toxin had, we believe, previously held the record with a lethal dose of 0 22 mg”

PROCEDURE AT THE ROYAL CANCER HOSPITAL (FREE)

At the outbreak of war the radium stocks of the Royal Cancer Hospital, in common with those of several other London hospitals, were buried in a specially constructed borehole extending to 50 ft below ground, at which depth the radium was considered safe even from a direct hit by a large calibre bomb At the end of November, 1939, however it was possible to resume to a restricted extent the use of radium in the treatment of patients Two of the three existing teleradium units (one 5 g and one 1 g) were put into commission and 0 5 g of radium in the form of tubes of various denominations was made available for use in surface radium and gynæcological applicators The third teleradium unit possessed by the hospital was so constructed that the radium, once in place, could not easily be removed

In order that the radium in these units could be quickly buried in case of air attack a second borehole (see figure) was constructed immediately *outside* the teleradium treatment room, which is situated on a second floor approximately 30 ft above ground level A steel tube 70 ft long was sunk 40 ft into concrete, the remaining 30 ft just reaching the sill of a window of the treatment room By removing the window and building a small cage outside, a radium table was formed just reached by the steel tube A simple wooden sliding door and steel plate which could be locked in position normally closed the top of the hole A special casket having three compartments and suspended from a steel hawser acted as a container for the radium The doors of the casket were so designed as to be closed and locked in position very quickly and securely. The three compartments were used for 5 g , 1 g , and radium tubes respectively A winch and series of pulleys completed the apparatus needed for raising and lowering the radium to and from the place of safety Several more complex systems involving motor driven hauling gear and pneumatic transference from bomb-head to borehole were carefully considered and rejected on the grounds of complexity, expense, and unreliability in an emergency The system chosen has worked well on all occasions

A R P drill was instituted a suitable set of rules and instructions formulated, and with practice it was found possible to return the 6 g of radium used in the units to the casket and to lower it out of sight in 15 sec About 45 sec sufficed to lower to the bottom of the borehole, the speed of the casket being controlled by pressure on the rim of the wheel of the winch The radium was lowered on the sounding of an alert and at the completion of treatments at the end of each day. Special holders were designed to aid in the rapid removal of the radium from the unit to the borehole



Until September, 1940 cancer of the skin and cancer of the uterus were treated by the appropriate types of applicator without any serious restriction For insertion into the tissues radon needles have been used at all times though recently (June, 1941) some radium needles have been put into use Owing to the continual air attacks on London in September, 1940 it was found advisable to abandon temporarily the use of radium in the form of surface or intravaginal applicators but treatment by teleradium continued without interruption The net effect of the day and night air-raids has been to restrict the number of cases treated, but in recent months it has been found possible to return once again to normal standards.

The treatment of skin cancer and cancer of the uterus by radium was resumed early in October, 1940 Radium applicators were employed for the cases of skin cancer The quantities used were relatively small, only one patient was treated at a time and treatment was always carried out during daylight hours As the patient was kept in a ward near the radium department these applicators could be quickly removed and transferred to the borehole when the occasion demanded, a special compartment being available in the casket The position with regard to intra-uterine and intravaginal applicators was rather different Continuity of treatment is important and the rapid removal of the applicators presents difficulties To remove applicators of this type every time a warning was sounded or to use radon instead of radium, would have made treatment impracticable, for transfer of the radium to a place of safety could not be effected quickly (that is, in less

[1] Evans, P D *Amer J publ Hlth* 1933 23 1017 , *Amer J Roentgenol.* 1937 37, 368 Aub, J C. Evans, R D Gallagher, D M and Tibbetts D M. *Ann intern Med* 1938 11, 1443

[2] Colwell, H A and Russ, S X ray and Radium Injuries, London 1934, p 178

than 2 min) and meanwhile a large quantity of radium would have been exposed to danger Secondly, radon supplies in the quantity necessary to treat any appreciable number of these cases are not readily or regularly available To meet this situation the following arrangements were made Not more than 90 mg of radium was ever left in use during an air-raid and the patient with intravaginal and intra-uterine radium was kept in a room by herself in the safest part of the hospital —the ground floor of a modern five-storey ferroconcrete building Responsibility for the safety of the radium was allocated in the event of enforced evacuation of the hospital, and rules formulated for other relevant emergencies In the circumstances it was felt that the chance of dissemination of radium salt enclosed in a double metal container and placed within the deep parts of the female pelvis were small even should the hospital sustain a direct hit, since only complete disintegration of the patient would cause loss of the containers and even then there was a reasonable chance of the metal containers remaining intact

PROTECTION OF PERSONNEL

Normally the conditions under which radium work is carried out are the subject of special and stringent recommendations laid down by international agreement Protective measures are taken to ensure that no radium worker receives radiation in excess of a certain minimum quantity (0 2 r per day) which is considered to be consistent with safety to general health It was obvious, of course, that repeated exposure to large quantities of radium under abnormal conditions imposed by the need for speedy removal of the radium to a place of safety meant that the staff responsible for this work ran the risk of receiving a dose of radiation greater than that considered safe By calculation and direct measurement it was found that the amount of radiation received by the staff still lay below the "tolerance dose," the average daily dose received by those taking part in the transference being about 0 1 r The special means adopted to ensure the maximum of safety under the new conditions were therefore briefly

1 Speed Rapid removal of the radium serves to reduce the time of exposure to a minimum

2 Distance The radium containers are kept as far as possible from the body during transference

3 Careful check is kept on the amount of radiation received during the duty periods of the members of the radium department An ionisation chamber is normally carried by each person employed in radium work at this hospital, and this check now becomes doubly important

4 Distribution of the risk among as many individuals as possible Initially a rota consisting of 8 members of the radium and physics departments was employed, but it was soon found possible to divide this work among fewer people without harmful result

As the result of the experience of eighteen months we have no reason, either clinical or physical, to question the effectiveness of the methods employed from the point of view of protection of personnel

WAR AND THE PATIENT

At various times since the outbreak of war patients requiring treatment by radium have undoubtedly suffered and some have even lost their lives as a result of the impairment of the facilities normally available during peace-time Patients undergoing radium treatment at the Royal Cancer Hospital at the outbreak of war had to be discharged, and, although it was found possible to recommence the treatment by X-ray therapy of some of these cases several weeks later, the remainder who could not be so treated have succumbed to their disease and the outlook of those who restarted was considerably affected For the first five months of the war no cases of cancer of the uterine cervix were treated by radium at this hospital With the possible exception of stage-1 cases, it is doubtful whether either of the alternative methods of treatment (surgery or X-ray therapy) can satisfactorily replace radium in the treatment of every type of case, so that the patients treated by these methods during the period in question must be considered as having had inferior treatment

The dispersal of population either as a result of deliberate evacuation to other parts of the country or migration to other parts of London because of air raids the shelter-life led by many patients of the hospital class since September, 1940, and the bombing of hospitals and temporary disorganisation of civilian medical practice have had the result that new cases coming for treatment are less numerous It was rare, for a time to see a hospital patient with an early lesion in certain body sites (buccal cavity, pharynx, cervix) In the two years preceding the war the number of early cases of disease in these situations attending for radium treatment had shown an encouraging increase, and there seemed reasonable hope that this was because the importance of early diagnosis and treatment was being realised by both patient and doctor If so, the war has largely nullified the work of years of careful and persistent propaganda just when tangible results were forthcoming

In normal times a waiting-list can be kept down to an unavoidable minimum, but since the outbreak of war the number of beds available for cancer cases at this hospital has had to be reduced with the result that the waiting list has increased Although during the quiescent periods of the war no time was needlessly lost in treating patients for whom the slightest hope of cure existed, since the onset of intensive air-raids it has on occasion proved difficult to arrange the admission of patients to hospital as rapidly as one might have wished Another point of importance is the difficulty in obtaining radon supplies at reasonably short notice This difficulty led to an early request by the honorary staff for the resumption of the use of radium needles, but no further action was taken at this hospital until recently

An efficient follow-up system is an essential part of any cancer service, its primary objects being to facilitate early detection of recurrence or of further metastases after treatment, and to permit correct assessment of late results of treatment and comparison of different methods of treatment It is thus a necessary adjunct to clinical cancer research The efficiency of this system at the hospital has for various reasons dropped from 95% to about 55% Many patients have evacuated Some have kept in touch with the hospital but many have neglected to do so Others have lost their homes as a result of enemy action, and have been very difficult to trace Private doctors are often of great assistance in providing information about patients who cannot attend regularly for examination In several cases these doctors are either on military service or have lost their surgeries by bombing so that it is difficult to make contact with them for information Other hospitals occasionally undertake the follow-up of patients living in their districts, and in some cases we have been deprived of follow-up information owing to the destruction of their hospital records Although outpatient sessions are held in the morning to save patients travelling during the blackout, difficulties of transport or fear of air-raids have prevented some patients reporting. We do not as yet know whether any of the untraced patients have been killed by enemy action, but it may be necessary to make allowance for cases of this kind in future surveys The effect on the patients of the lack of regular supervision is seen from time to time when an untraced patient ultimately appears with an advanced recurrence, having delayed coming for one of many possible reasons connected with the war

Even in normal times, with a full range of foods to choose from, the feeding of patients undergoing teleradium treatment for cancer in the head and neck region is fraught with difficulties Not only does the treatment induce anorexia and perversion of taste but reactions in the irradiated mucous membranes give rise to dryness, pain and dysphagia Ordinarily, semi-solid or fluid diet containing eggs, milk, fats and carbohydrates of high caloric value form a basic food designed to supply 2000 Calories per day, which is considered the minimum requirement for these patients But in spite of difficulties in obtaining many of the common items, the culinary ingenuity of the nurses responsible for feeding these patients has been such that no patient has suffered as a result of the shortage

Two other points deserve mention Most of those undergoing teleradium treatment are inpatients, and during periods of intense air-raids are often concerned about the welfare of their relatives This worry, added he mental depression usually associated with the g and tedious course of the treatment, affects ersely the well-being and equanimity of many ients They become irritable and non-coöperative, n at a time when full cooperation is imperative, l when the actual treatment is completed they hasten ne long before their reactions have subsided or they fit to go As home often means a public shelter at ht, the chances of a debilitated patient succumbing to intercurrent infection is high, and we have noted the ith soon after leaving hospital of 2 patients who uld probably have survived had they remained in spital until they were fit to go For treatment of ncer by irradiation to be effective regard must be id to the time over which the treatment is spread ny appreciable interruptions or delays in the ordered ntinuity of treatment diminish its value Several nes since September, 1940, patients have interrupted eir treatment to return to their homes—or erst-while mes—because of a tragic domestic sequel to an air-id In a few cases when the patients have not turned to complete the treatment it is certain that ey will succumb to their disease Where the patients ve returned it is as yet too early to assess the precise fect the delay may have on the ultimate response to eatment

We would like to acknowledge our gratitude to the members our staffs who have carried on their normal and abnormal ities under very trying circumstances, and have thereby abled radium treatment to be continued in this hospital In rticular we would mention Miss E W Glazebrook, sister in ie radium department and Dr J R Clarkson of the physics epartment The accessories to the borehole were constructed y Messrs H Hodt, senior and junior, technicians to the hysics department

NTERNATIONAL STANDARD FOR VITAMIN E

An international standard for vitamin E has been stablished and, as in the case of the international standrds for vitamins A, B_1, C and D, the National Institute r Medical Research, London, acting on behalf of the ealth Organisation of the League of Nations, has underaken its supply to laboratories, institutes and research orkers throughout the world

Synthetic racemic α-tocopheryl acetate ($C_{31}H_{52}O_3$) as been adopted as the international standard for itamin E The investigation of the chemical, physical nd biological properties of this substance, its suitability r adoption as the international standard and the manner of its application in biological assay was carried out, t the request of the Health Organisation of the League f Nations, by the vitamin E subcommittee of the ccessory food factors committee of the Lister Institute nd the Medical Research Council The subcommittee ere able to enlist the coöperation of experts in fourteen aboratories in Europe and America, and have recommended the adoption of synthetic racemic α-tocopheryl cetate as the international standard They further ecommend that the international unit for vitamin E hould be defined as the specific activity of 1 mg of the andard preparation, this being the average amount hich, when administered by mouth, prevents resorption-estation in rats deprived of vitamin E

In normal times the results of the cooperative investigaon would have been submitted for discussion at the ird international conference on vitamin standardisaon, which had been arranged for the autumn of 1939, ut because of the war this conference was not held he report and recommendations of the subcommittee ave, however, been placed before the members and fficers of the League of Nations' Permanent Commission n Biological Standardisation and of the International onference on Vitamin Standardisation, who were availble, and they have accepted the responsibility of adoptng the proposed standard for vitamin E, accepting the ecommendation defining the international unit, and uthorising the National Institute for Medical Research o proceed with the distribution of the standard

The international standard for vitamin E is issued as solution in olive oil of which one international unit is ontained in 0 1 g In countries where national ontrol centres have been established it will be supplied to their directors for local distribution · it will also be supplied to laboratories, institutes and research workers in this country, and in countries in which national control centres have not yet been set up Application should be made to the department of biological standards of the National Institute for Medical Research, Hampstead London, N W 3

MEDICINE AND THE LAW

Illness after Hotel Lunch

CATERING establishments do not guarantee the health of every visitor to whom they serve a meal Actions for damages are sometimes brought by visitors who have felt ill after eating at a restaurant or hotel They do not always succeed , *post hoc* is not necessarily *propter hoc* In the recent county court case of Braham *v* Grand Hotel, Birmingham, a lady gave evidence that while eating steak and kidney pie at the hotel, she found something unexpectedly solid in her mouth She thought it might be a piece of tooth , it turned out to be a chip of crockery That night, she said, she woke in great pain , there was medical evidence that she was suffering from food poisoning She claimed damages for breach of warranty of the quality of food supplied , alternatively she alleged negligence in allowing the food to become contaminated On the other hand the defendants denied that the food was defective or that their staff had been negligent There seemed no necessary connexion between the chip of crockery and food poisoning They had served nearly a hundred portions of steak and kidney pie that day, and this was the only complaint The city bacteriologist found no poisonous organisms in the pie The judge disregarded the crock He found no indication of slackness in the conduct of the hotel The only suggestion against the pie was that the plaintiff was ill after eating it it would be unsafe to say that the illness was due to the hotel luncheon Judgment for the defendants with costs

NEW OFFICIAL NAMES FOR DRUGS

THE General Medical Council has issued a further list of approved names for drugs which are now produced or likely to be produced in this country

Approved name	*Other names*
Amethocaine hydrochloride	Decicain
Menaphthone	2-methyl-1 4 naphthoquinone
Pethidine hydrochloride	Dolantin
Soluble phenytoin	Epanutin, Eptoin, sodium diphenylhydantoinate, Solantoin, Soluble Dilantin
Sulphacetamide	Albucid

The council hopes that these and the approved names previously published [1] will be generally adopted

ORTHOPÆDIC CONFERENCE AT ROEHAMPTON

A CONFERENCE of the orthopædic surgeons attached to the Ministry of Pensions hospitals was held at Queen Mary's Hospital, Roehampton, on Sept 24–26, Mr G R Girdlestone, honorary consultant to the ministry, presiding Clinical rounds were conducted by Mr Pomfret Kilner and Mr George Perkins, and Mr Fraser demonstrated the methods used by himself and Mr Kilner in fractures of the jaws Dr R D L Kelham, surgeon in charge of the limb fitting department, assisted by Captain Maxwell, gave lecture-demonstrations on modern artificial limbs, and explained the present-day sites of election—for an above knee amputation 10 in below the tip of the greater trochanter , for a below-knee amputation 5½ in below the level of the knee-joint on the medial side , for an above elbow amputation 8 in from the acromion process , and for a below-elbow amputation 7 in from the tip of the olecranon Surgeon Lieut -Commander John Bunyan, R N V R , showed a cinematograph film of the results of treating burns by irrigation with electrolytic sodium hypochlorite in the Stannard bag, and afterwards demonstrated his procedure on patients from the Queen Alexandra Hospital, Cosham, and other cases with septic amputation stumps and wounds The conference provided an opportunity for exchanging views on orthopædic treatment and coördinating the work being carried out in ministry hospitals

In England Now

A Running Commentary by Peripatetic Correspondents

THE call was for blood—human blood It all began in the early summer of 1939 when a well-known radio commentator asked a responsive public to report for service at their nearest hospital What was to be done with all these volunteers? Were they to be admitted to our select body of hospital donors or were they to constitute a "national emergency panel—Garumchester (pronounced Gumster) branch" We decided on the latter course In the rapidly growing queue outside the pathological department the secretary discerned some of Garumchester's leading citizens, including civic and legal dignitaries, a retired aristocrat of the Church and another volunteer entitled to wear a small size in coronets "Am I to enter them all for Wassermanns?" she asked betraying her concern at the serodiagnostician's lack of discrimination Our senior technician remarked that an occasional transfusion of luetic blood would make little difference after three or four years of total war, but his implication was considered to be both unjust and cynical "Why not wait and do the Wassermann when you take the blood?" he said, "the fact that they are negative now doesn't mean that they will be after a couple of years of war Anyway, what's arsenic for?" The essential wisdom of his remarks was accepted and the volunteers were rapidly reviewed, being let off with an inspection of the arm veins and the token donation of two or three drops of blood for the grouping test We closed the laboratory that evening with schemes already afoot for running the department on a war basis If the worst happened pathological investigations would have to be rationed, clerical work curtailed and all reports shortened We sincerely hoped war would not come but we were resolved that if it did there should be no deterioration in our ability to aid in the diagnosis of venereal disease "Do you mind if I slip off a little early tonight," asked the senior technician, "to plant a few more rows of winter greens for the guineapigs We can't afford to let the complement fall below 0 08 in war-time," he added, "and an intensive course of purple sprouting before the breeding season is beneficial, if it comes to that, it wouldn't do me any harm myself"

This is a war of battles The Battle of the Blood Groups is still on We were all asked to adopt the League of Nations classification and most of us did, bearing the genial sarcasm of the more senior clinicians "In my day, my boy, 1, 2, 3 and 4 were good enough for us, why alter it?" "But, my dear Hornbeam, the newly adopted classification does tell me the agglutinogen content of the corpuscles, and therefore I find it preferable to the Moss and Jansky schemes which lead only to confusion" "I should forget about those—those things you were talking about," rejoined our pathologophobe, emphasising his remarks with the instrument of precision which is habitually suspended around his neck, "we always managed to transfuse without them before you came here and if you take my advice you will not alter the present arrangements Of course, transfusion came in after my day, but I have watched it develop" "Did you ever run across James Blundell, of George's, sir? He was one of the first on the job" "I used to go there quite a lot when I was dressing at Ananias's," he replied, "but I don't recall him" "He may have been after your day," I rejoined cautiously "He wasn't born till 1790"

Many of us have met this unwillingness to accept the international classification, the compromise which most have adopted is to give that of Moss first followed by the international version in brackets The more daring have reversed the procedure and told our printers to lighten the bracketed numbers with each succeeding impression The dual system of nomenclature has raised misgivings in some donors, who don't much like belonging to group B3 "I live a healthy out-of-doors life and never had a doctor since my last baby, but Mrs J around the corner in Plaice St has blood which the doctor said is very rich—he called it A1—and she isn't nearly so particular as to what she eats Tell me, doctor, what I ought to take to make my blood A1?" What a blessing the Geneva tribunal didn't ordain A, B, C and D for the groups! C3 blood would have taken explaining away

* * *

In our area is included what must surely be the delightful small country town in England, far forgotten by the poets In this charming comm the keenness for the blood-transfusion service exc anything previously seen, and on a warm day in J we enrolled close on 8% of the population as don The local organisers were surprised at the success of t scheme and were anxious to reach a certain n number A request was therefore sent to the c nearby, the pub opposite and the adjoining dance hal The response was gratifying The cinema interrup its performance while the visitors, led by the jo manager and the bar-tender, with his thirsty follow filed in to be tested before resuming consumption films and drinks Later, on this summer evenin procession of men and girls from the dance hall arrive the girls still wearing their cool and colourful evenin frocks Afterwards we were able to report that th required number had been exceeded

Most of our donors hide their lamps under bushel A few of them however, are fussed over by anxiou relatives who are assured by the victim that althoug it wasn't too bad the fact remains that he is now workin with a pint less blood than before, but that he doesn intend to let the work suffer for it and he will see that it i done just the same It requires more than average human effort of will to discourage the hero worshipper But this type of donor, who is fortunately rare, may do much to delay recruiting in a small community, and embarrass the machinations of the local hæmophilist On the other hand, we have met with many instances which reflect great keenness to serve, as well as personal courage There was the youth who had recently lost an arm in an accident and whose other arm was ankylosed to an angle which would have made it wellnigh impossible to insert the needle The deaf, the lame, the blind and even the paralysed have visited us to give their donations We have had to reject many who were too ill—a woman with carcinomatosis, a girl in an advanced state of phthisis and an old man with heart failure, he had been compelled to abandon munition work and had chosen this alternative form of national service In one hamlet no less than fifty near neighbours assembled in a farmhouse kitchen on a Sunday evening in late spring and braved a deluge to get through An old lady who was rejected because of ill health burst into tears

One afternoon in winter we were due to group inhabitants of a few lonely hamlets pocketed away in the hill Our hostess's suggestion to "bring chains" seemed to u in the town sixteen miles away rather fatuous, but we were glad of her advice and only after a hazardous an circuitous route did we reach the house Our fears tha the volunteers would not venture through the storm were dispelled by our hostess who assured us that they would all come—as indeed they did They came throug driving snow and the blackout, fine hefty farm lads, lar girls and farmers' wives, all ready to give first-aid to th blitzed cities We have had girls of fifteen and sixtee posing as eighteen in order to be accepted, and old m and women taking off ten years or so, and what a goo response we have had from ex-Service men of all ranks In fact, there is no section of the community which ha not responded, while friendly, neutral and enemy alie have come forward equally well It is particularly gratifying to enrol people who have themselves been transfused at some time in the past and are now ready to pay back Evacuees and especially those from the bombed areas are amongst our keenest customers One woman had come over from a nearby town, temporarily disorganised after a heavy raid, in order to shop, she was so delighted at her successful forage that she came along to show her appreciation by an offer of blood We had a visit from a member of the London A F S who had been sent down for a week's rest He was so grateful to the inhabitants for the hospitality they had shown him that he came along to give a donation of blood to the local bank by way of repayment He wrote later "How are your blood donors, are they rolling in, or do you sit patiently gazing at your samples, waiting for a custom to call? Should the patient who had my blood ev complain of hearing fire-bells, just tell him it is a fa

Don't forget, doc, if you want more just let me and I'll be right on the spot Funny thing, hardly gave hospitals a thought until that day, then I ed that every day there are patients and children P S Your blackout is deplorable "

* * *

r tortuous ways a copy of the *Deutsche medizinische henschrift* for Sept 5 has come into my hands and I eagerly scanned the page of *Kleine Mitteilungen* iews stories) which is all that this fat medical weekly ys itself to tell of current happenings in *Gross- schland* Pride of place is given to an announcement final medical examination next June under the new ilations which prescribe two preclinical and two ical years or four years of medical study after military labour service are over The old regulations remain force at Vienna, Graz and Innsbruck Women lical students will be allowed to count emergency sing as part of the prescribed course in place of factory agricultural service Then we are told that the *ırer* has set up in Berlin under Home Office control an cial institute for assessing vitamins and finding new s There was to be a three-day festival in Salzburg Paracelsus with foreign guests and a gala performance Goethe's "Faust," followed by a two-day conference the Alpine climate, opened by Dr Conti, medical ector-general, and covering besides physiology, ychology and the inevitable raciology, such things as pnotic drugs, sulphonamide therapy and the treatment sterility A ten-days course at Alt-Rehse has the tonishing title of "The totalitarian idea in dentistry," th lectures on chewing gymnastics, relaxation therapy d psychopathology of artificial dentures, as well as the ore familiar focal infection Scanty university news eked out with some trifling honours to Prof Paul iepgen in Buenos Aires and Bucharest, and the 70th rthday of Prof Birch-Hirschfeld Book announce- ents include the final instalment (bibliography) of imann and Myrbäck s "Methods of Ferment Investiga- on," a new study of the anti-tuberculosis campaign, o small practical books on diabetes, a standard work on e public-health doctor, and a new edition of Schede's Hygiene of the Foot " Not very exciting, you may say, it nevertheless a rough sketch of the background of edicine in contemporary Germany But one of my llow peripatetics might have made more of it

* * *

I was rather surprised to hear the other Sunday that e Brains Trust had no idea why man enjoyed music oviously man's acoustic apparatus was not formed for aring his own and other people's voices It was rmed for defence, though for this purpose, in modern mes when auditory awareness is not of such vital cessity, it has atrophied As natural man or any her animal moves about he is surrounded by a myriad oises, the manifold rustlings of the vegetable world, the ppling of the poplars, the harsh whisper of the holly, the y-sand sound of the acacia, a vast insect orchestra, ie song of sea or river, animal and bird calls, and the oise of his own movements As a babe he was frigh- ıned of some of these noises, but gradually one by one admitted them as friendly noises, until their number as so large that he couldn't give them individual atten- on, so, probably by allowing entrance to a note here id there from each, he blended them into a pattern his pattern of friendly noises surrounded him in his aking hours and to some extent in his sleep (Most ulors wake up if the ship's engine stops when they re asleep) This pattern is a protection, like tentacles ıst near and far, for the approach of an enemy or even ie sudden cessation of one of its constituents would reak the pattern and put him on the alert and in a mild ate of fear The hearing of the pattern then meant ıfety Modern man uses the same mechanism though ot so often for defence, he can turn what he knows to e a harmless and friendly railway train's noises into a hythm—arankatitanka-titanka He can turn his own ıreless blare into a soothing background of sound, hough he has much more difficulty with his neighbour's hich he feels to be hostile Absolute silence, which a rarity in the natural world and meant to man that e was without his acoustic protection, still brings a eeling of awe Incidentally in tinnitus there is a great effort on the part of the pattern-making mechanism to turn the intrinsic stimulations of the cochlear nerve into friendly noises—"wind in the chimney ' and ' an outboard motor with an occasional mis-beat " are the last two in my case-book Now music, and to some extent verse, not only gives a well-ordered pattern of noise and therefore a feeling of safety, but it does so ready made, without any strain on the pattern-making mechanism, leaving the other emotions, uninhibited by fear, free to have a binge Why precisely "Rule Britannia " should make one want to cut throats and Handel's Largo to ooze altruism probably depends on memories, words or suggestions associated with their particular chords Elementary, my dear Julian!

* * *

It is traditional that a doctor is unwise to treat the members of his family, from which arises some of the difficulty about repaying a colleague for kindness I have never held this view, the unwisdom supposes that the medical husband and father is either unable or unwilling to approach the case detached or that he finds it irksome to regard such a patient in terms of anatomy, physiology and pathology Maternal anxiety may be the cause of much of this The same doctor, however, essays the correct approach to those non-family patients with whom he is on terms of close social intimacy How many doctors find it inconvenient to make an internal examination of a constant bridge partner? If for no other reason than this, the plight of such a patient justifies the existence of the independent consultant group Years ago as I was leaving home one morning my neighbour, a London surgeon, told me almost casually that his wife's bowel was resisting enemata the number had reached seventeen I knew nothing of her medical past, which included operation for ovarian cyst, but I murmured equally casually that a band might be the cause On my return in the evening the ambulance was at his door and a surgeon ready at the nursing home, but she died that night Lately I have myself had the care of a doctor's wife at a distance He has no colleague within ten miles and more, on the eighth day he asked me to come over I found lobar pneumonia, with the crisis yet to come in spite of his sulphapyridine He had not been able to diagnose pneumonia for certain because his wife was still about and had declined to permit him to investigate

* * *

'You are going on holiday next week?" I inquired "Aye, next week, Sir," replied John, the senior laboratory attendant adjusting the time-marker 'Rothesay?" "Aye" "The children will be very excited?" I ventured "Aye they are so ' "And what about yourself, John—do you still enjoy a seaside holiday?" "Aye," he said again, but this time his tone implied serious reservations He was obviously uneasy His answer would need elaboration I watched the struggle between his innate reticence and his Covenanter's zeal for truth At last he looked up "Doctor" he began "Yes?" "Shall I tell ye what I consider to be the best part of ma holiday?" he asked solemnly "Do!" I exclaimed enthusiastically, and settled down to listen Would the high spot be the morning stroll along the promenade? Sun-bathing? No, I felt sure that John would frown on that, but I was prepared to hear that in moments of complete abandon he might go so far as to paddle with the three weans ' Well Sir," he proceeded, as a faintly ecstatic expression crept into his face, "the best moment is when the train draws into Central Station when we return to Glasgow Man, ' he added almost fervently, "yon's a grand smell!"

* * *

The registrar, being in a reminiscent mood, launched into an account of the death certificates which he had returned to the hospital First came the surprising death of John Smith, aged 3 days, from chronic bronchitis and senility, and, on the same day of William Brown, aged 86, from intracranial hæmorrhage due to birth injury Then came the form, satisfactory in all respects except for the completion of the section "qualification" Here the worried doctor, straight from a pneumonia ward had started with M B and then drifted to 693 A useful qualification, perhaps, for this day and age.

Parliament

Post-War Hospital Policy

In the House of Commons on Oct 9, in reply to Sir FRANCIS FREMANTLE, the MINISTER OF HEALTH said The question of post-war hospital policy and reorganisation, more particularly in relation to the Emergency Hospital Scheme, has for some time been engaging the attention of the Government While any immediate reorganisation must be regarded as impracticable in present circumstances, certain broad principles can be laid down as the basis of Government policy

It is the objective of the Government as soon as may be after the war to ensure that by means of a comprehensive hospital service appropriate treatment shall be readily available to every person in need of it It is accordingly proposed to lay on the major local authorities the duty of securing, in close cooperation with the voluntary agencies engaged in the same field, the provision of such a service by placing on a more regular footing the partnership between the local authorities and voluntary hospitals on which the present hospital services depend The Government recognise that to achieve the best results and to avoid a wasteful multiplication of accommodation and equipment it will be necessary to design such a service by reference to areas substantially larger than those of individual local authorities It will be the aim of the Government also to avoid overlapping and uneconomical expenditure by securing the provision of the more highly specialised services at teaching hospitals and other centres selected to serve these wider areas, and by arranging for a proper division of function between hospitals in these areas

With regard to the financial aspects of the Government's proposals, it is their intention to maintain the principle that in general patients should be called on to make a reasonable payment towards the cost whether through contributory schemes or otherwise In so far as any new burden may be thrown upon local authorities in providing or maintaining hospital accommodation, or in contributing towards the expenditure of voluntary hospitals, a financial contribution, the extent of which will be a matter for further consideration, will be made available from the Exchequer Special arrangements for dealing with the teaching hospitals by way of increased educational grants are in contemplation

In present circumstances the arrangements for hospital services must be determined by war-time requirements, but the Government are anxious to take every step to avoid any unnecessary delay I have already had preliminary discussions with the bodies representing the municipal hospital authorities and the voluntary hospital movement and I am hopeful that these discussions will be continued With their concurrence I am instituting a survey of hospitals in London and the surrounding area, to provide the information needed as a basis for future plans As regards the remainder of the country, valuable preliminary work has already been done in some areas by bodies representing both the municipal and voluntary hospital authorities, in particular, by an organisation formed under the auspices of the Nuffield Provincial Hospitals Trust In any surveys which it may be found necessary to institute in the provinces I shall have full regard to the information already available in this way, which I am glad to know will be at my disposal for the purpose

Mr BROWN added that the aims of future policy in Scotland were generally similar, but that certain important differences in the Emergency Hospital Service and in the methods of financing voluntary hospitals in Scotland were being given special consideration

Man Power and the War Effort

Man power is the beginning and the end of our war effort and a debate in the Commons on Oct 8 brought out clearly the difficulty of striking a fair balance between the needs of industry and of the services As Mr GRAHAM WHITE pointed out, not only must we equip our men but we must man our equipment He appealed to the Government not to confuse time with eternity and he warned them that the fabric of distribution by the food trade was wearing thin It was no less important to fill men's stomachs than to fill shells He did not think the Industrial Research Board was being given a fair opportunity of working out the best of work for different jobs Miss MEGAN LLOYD G deplored the fresh call-up of land-workers, for there may be an alternative between guns and there is no alternative between guns and bread felt that the production of red tape was still one major industries and asked for firm treatment of th and select company of shirkers and for the adm women as partners, and not as conscripts, in the gr struggle our country has ever faced

Replying Mr ERNEST BEVIN said that no co not even Germany, has tried what was virtually compulsion of women as we have tried But in han women you must proceed gently and have regard f parents He was coming to the conclusion that reservation would have to go and that individual re tion would have to take its place He wished that process of training and manning the country had t place in peace-time and not in war-time He would h liked to see a double-purpose army where the w nation was trained both for fighting and product But such a policy could not be achieved if the War O was completely scrapped in peace-time and the Gov ment was expected to improvise a military machine carry out gigantic tasks in fifteen months

QUESTION TIME

Priority Milk

Replying to a question Major G LLOYD GEORGE said th on the recommendation of the Special *Diets Committee*, th milk supply scheme (see p 473) makes provision for a wid range of sick persons than the scheme for regulating distribution which has operated throughout the summer The arrangements for expectant mothers, children and adolescents are also based on the advice of nutritional experts

Domestic Staff Difficulties

Miss E RATHBONE asked the Minister of Health wheth he was aware that many voluntary hospitals were seriou hampered, and some may even have to close down wholly o partly, owing to lack of ancillary staff such as stokers, porte and ward maids, and as the work of these hospitals w work of national importance he would assist them by annou ing this and by devising, in cooperation with the Ministry Labour, some method of aiding the hospitals to obtain t necessary staff —Mr E. BROWN replied I have for so time been concerned with these difficulties and I have recent discussed them with representatives of voluntary hospital Domestic work in hospitals is recognised as one of the serv of most urgent national importance for which recruitment to be carried out by the Minister of Labour, and I have is a poster for circulation to hospitals to make this importan clear to those already employed in hospitals

In answer to a further question from Sir F FREMANTL Mr BROWN added that women, including domestic st employed in child welfare institutions are performing a ve important national service and one which should offer spec attraction to older women I am assured, he said, by t Minister of Labour that there is no present intention of call them up for selection interview within the age groups cov by the Registration for Employment Order

Return of Tuberculous Soldiers

Mr T E GROVES asked the Secretary of State for War he was aware that orders had been issued by his departm for 40 tuberculous military cases in the Addington Hospit Natal, and 120 similar cases at Oribi, to be returned to th country, and whether he would state the arrangeme made for the reception, distribution and maintenance o these cases when they arrived in this country —Capta H D R MARGESSON replied No special instructions ha been issued by the War Office regarding these cases, and I presume that Mr Groves refers to general instructio regarding the return to this country from South Africa o soldiers suffering from tuberculosis On arrival in th country soldiers suffering from tuberculosis are sent to military hospital where they receive treatment as necessar until they are handed over to the care of the local healt authority

Coroners in England and Wales

Replying to Dr RUSSELL THOMAS Mr HERBERT MORRI said There are 297 coroners in England and Wales of who according to my present information, 13 are employed on full time basis Several coroners occupy more than o ership, the total number of coronerships being 333 aggregate salaries of all coroners for 1939 amount to 07, and the expenses incurred by them in the execution eir duty to £145,666

Pensions for the Blind

ROBERT YOUNG asked the Minister of Health whether as satisfied that the purpose for which the pensionable of a blind person was reduced from 50 to 40 had been sed or whether his attention had been called to the extent hich local authorities had caused the financial benefits of amended act to be reduced or cancelled , and what steps roposed to take to give to eligible blind persons the fit intended for them —Mr BROWN replied It was ys contemplated that a local authority in granting finan- assistance to a blind person under the Blind Persons Acts ld take into account the amount of any old age pension ived by him , and one of the objects of reducing the sionable age for blind persons was to secure that the den of providing assistance to blind persons should be ed between the Exchequer and the local authorities

Exemption from Billeting

r E H KEELING asked the Minister whether he was re that a large proportion of the householders in Harrogate n whom evacuees had been billeted had submitted lical certificates recommending that they be taken off the eting list , and whether such certificates were being epted.—Mr BROWN replied I am aware that a number ouseholders in this district have submitted medical certifi- es to support a claim to be relieved of the responsibility accommodating billeted persons In such cases the seholder is informed that he has the right of appeal to the l tribunal set up under the Defence (Billeting Tribunal) les, 1939 , and it is for the tribunal to decide whether exemp- n from the acceptance of billeted persons should be granted

---

Public Health

From the School Reports

NOTTINGHAM

THE medical inspection subcommittee of Nottingham's ucation committee in 1940 consisted of eight members, o of whom, the chairman and one woman councillor, e doctors The staff consists of Dr Arthur Newth, nior medical officer for education, Dr R G Sprenger, nior assistant, 4 other full-time assistants, 7 part-time ecialists 7 dentists , then there are a part-time chiatrist, 2 educational psychologists, a speech- erapist and a social worker attached to the child- idance centre , and finally 8 nurses and a full comple- ent of clinical assistants, dental attendants and clerks hese attend to the medical needs of the 36,000 school- ildren of the city In connexion with the evacuation heme a survey of the children made it possible to test e completeness or otherwise of the record of defective ildren Beyond some bed-wetters and children with ehaviour troubles, few defectives were found who were ot already known " A large number of cases were ported as having some serious condition such as heart kidney disease or tuberculosis which was found not be present when the child was last examined This pports the idea that the avoidance of invalidism is a ot unimportant function of the school medical service "

is of course possible that some of these chronic invalids ' had developed serious disease since their st examination, but presumably the passage means that ey had not done so Generally a survey of children sent from school for long periods reveals that the great ajority are not suffering from any disease to warrant eir non-attendance, a few are found with lesions which ake them suitable for special education which it is the ity of all education authorities to supply and the mainder an extremely small number, are either dying incapable of survival beyond the school-leaving age he number of children whose lives are wrecked because mebody has detected an innocent heart murmur or bumınuria greatly exceeds that of those destroyed by sease This is one of the major truths of the school edical service

Dr Newth, in discussing the increase of scabies, which ottingham shared with most parts of the country calls that in the last war there was a similar increase ften associated with the return of a soldier on leave , but the present epidemic started before the war, even before conscription, and the incidence of scabies in those serving in the Forces in this war has not been severe He says that scabies occurs chiefly among unclean people, but the connexion is not direct , scabies infection is, in fact, very common in clean people, but in them the mite is soon dislodged, so we very rarely see anything more than a deserted burrow except in the dirty In contrast to scabies, body lice are rarely found in school-children, even those of the dirtiest and most neglected families "Towards the end of 1940 one began to notice a deterioration of the clothing of some of the children " but their nutrition was maintained at an excellent level Dr Newth says he cannot understand the mentality on the part of a mother ' who, having made the brave decision to send her child overseas, withdrew her application when she was told that dental treatment was essential "

SMETHWICK

Dr Hugh Paul says that the outstanding feature of the year was the continuing high standard of physical and mental health which was maintained throughout " Even the sustained night bombing of the last quarter failed to have any visible adverse effect on the children " It seems likely that the unprecedented high level of health and nutrition which we reached before the outbreak of war largely accounts for the comparatively slight effect air-raids have had on the health and morale of our people If so, it means that in the end the butter will beat the guns

Among 8254 school-children of Smethwick, 74 were in 1940 referred to the chest clinic for suspected or possible tuberculosis Of these, one was found to have definite pulmonary tuberculosis and one another form of the disease, 61 were excluded as not tuberculosis, and 11 were suspected of possible pulmonary tuberculosis Suspected pulmonary tuberculosis in children and adolescents is one of the most difficult medical problems of the present day To make a positive or negative diagnosis where this cannot be better than a guess may easily be disastrous for if it is wrong it must lead either to unjustified invalidism or to the loss of opportunity to avert a fatal disease How to keep a suspect under supervision without creating invalidism is a problem medicine has not yet solved, yet in theory it is easy and the most useful work that a physician can do

KENT

In the second half of 1940 Kent became a battlefield, so what had been a reception area had many shifts in school population The part of Kent which for education is administered by the county remained in the main a reception area, but the coastal towns which are their own education authorities had many vicissitudes, with the result on the county that though the school population remained fairly constant in numbers, it was much disturbed Moreover, the county was subject to repeated air-raid warnings, so the children passed much of their time in shelter conditions Yet, from Dr J W Fox's report, presented by Dr Constant Ponder, the children's health and spirits did not suffer appreciably, and from the school medical statistics of the year it would not be possible to tell that anything unusual had happened Dr Fox gives a brief but most interesting note on the improvement in nutrition of evacuees as measured in terms of growth This is striking and widespread, and is not wholly explained by the change from town to country life " The evacuees compare favourably with native children Perhaps the same can be said where Kent children have gone " Change, in itself, seems to be favourable and Dr Fox suggests as a permanent feature of education periodic exchanges of children from one district to another

The Kent dental scheme does not yet make general provision for the treatment of pupils in secondary schools but this is available to some extent The senior school dentist in his report remarks that in some schools the parents though unable to afford private dental treatment do not take advantage of the clinics with results that are deplorable " Many of the pupils at these schools present an appalling amount of gross oral sepsis " He attributes this refusal to accept treatment to " a curious form of snobbery, either on the part of the parents or, more frequently, of the children themselves "

Parliament

Post-War Hospital Policy

In the House of Commons on Oct 9, in reply to Sir Francis Fremantle, the Minister of Health said The question of post-war hospital policy and reorganisation, more particularly in relation to the Emergency Hospital Scheme, has for some time been engaging the attention of the Government While any immediate reorganisation must be regarded as impracticable in present circumstances, certain broad principles can be laid down as the basis of Government policy

It is the objective of the Government as soon as may be after the war to ensure that by means of a comprehensive hospital service appropriate treatment shall be readily available to every person in need of it It is accordingly proposed to lay on the major local authorities the duty of securing, in close cooperation with the voluntary agencies engaged in the same field, the provision of such a service by placing on a more regular footing the partnership between the local authorities and voluntary hospitals on which the present hospital services depend The Government recognise that to achieve the best results and to avoid a wasteful multiplication of accommodation and equipment it will be necessary to design such a service by reference to areas substantially larger than those of individual local authorities It will be the aim of the Government also to avoid overlapping and uneconomical expenditure by securing the provision of the more highly specialised services at teaching hospitals and other centres selected to serve these wider areas, and by arranging for a proper division of function between hospitals in these areas

With regard to the financial aspects of the Government's proposals, it is their intention to maintain the principle that in general patients should be called on to make a reasonable payment towards the cost whether through contributory schemes or otherwise In so far as any new burden may be thrown upon local authorities in providing or maintaining hospital accommodation, or in contributing towards the expenditure of voluntary hospitals, a financial contribution, the extent of which will be a matter for further consideration, will be made available from the Exchequer Special arrangements for dealing with the teaching hospitals by way of increased educational grants are in contemplation

In present circumstances the arrangements for hospital services must be determined by war-time requirements, but the Government are anxious to take every step to avoid any unnecessary delay I have already had preliminary discussions with the bodies representing the municipal hospital authorities and the voluntary hospital movement and I am hopeful that these discussions will be continued With their concurrence I am instituting a survey of hospitals in London and the surrounding area, to provide the information needed as a basis for future plans As regards the remainder of the country, valuable preliminary work has already been done in some areas by bodies representing both the municipal and voluntary hospital authorities, in particular, by an organisation formed under the auspices of the Nuffield Provincial Hospitals Trust In any surveys which it may be found necessary to institute in the provinces I shall have full regard to the information already available in this way, which I am glad to know will be at my disposal for the purpose

Mr Brown added that the aims of future policy in Scotland were generally similar, but that certain important differences in the Emergency Hospital Service and in the methods of financing voluntary hospitals in Scotland were being given special consideration

Man Power and the War Effort

Man power is the beginning and the end of our war effort and a debate in the Commons on Oct 8 brought out clearly the difficulty of striking a fair balance between the needs of industry and of the services As Mr Graham White pointed out, not only must we equip our men but we must man our equipment He appealed to the Government not to confuse time with eternity and he warned them that the fabric of distribution by the food trade was wearing thin It was no less important to fill men's stomachs than to fill shells He did not think the Industrial Research Board was being given a fair opportunity of working out the bes of work for different jobs Miss Megan Lloyd deplored the fresh call-up of land-workers, for there may be an alternative between guns and there is no alternative between guns and bread felt that the production of red tape was still one m major industries and asked for firm treatment of th and select company of shirkers and for the admiss women as partners, and not as conscripts, in the gr struggle our country has ever faced

Replying Mr Ernest Bevin said that no co not even Germany, has tried what was virtual compulsion of women as we have tried But in ha women you must proceed gently and have regard f parents He was coming to the conclusion that reservation would have to go and that individual r tion would have to take its place He wished th process of training and manning the country had place in peace-time and not in war-time He would liked to see a double-purpose army where the w nation was trained both for fighting and produc But such a policy could not be achieved if the War O was completely scrapped in peace-time and the Gov ment was expected to improvise a military machine carry out gigantic tasks in fifteen months

QUESTION TIME

Priority Milk

Replying to a question Major G Lloyd George said t on the recommendation of the Special Diets Committee, th milk supply scheme (see p 473) makes provision for a wid range of sick persons than the scheme for regulating distribu tion which has operated throughout the summer The arrangements for expectant mothers, children and adolescents are also based on the advice of nutritional experts

Domestic Staff Difficulties

Miss E Rathbone asked the Minister of Health wheth he was aware that many voluntary hospitals were seriou hampered, and some may even have to close down wholly o partly, owing to lack of *ancillary staff* such as stokers, port and ward maids, and as the work of these hospitals w work of national importance he would assist them by anno ing this and by devising, in cooperation with the Ministry Labour, some method of aiding the hospitals to obtain t necessary staff —Mr E. Brown replied I have for so time been concerned with these difficulties and I have rece discussed them with representatives of voluntary ho pi Domestic work in hospitals is recognised as one of the serv of most urgent national importance for which recruitm to be carried out by the Minister of Labour, and I have a poster for circulation to hospitals to make this importa clear to those already employed in hospitals

In answer to a further question from Sir F Fremant Mr Brown added that women, including domestic employed in child welfare institutions are performing a v important national service and one which should offer spe attraction to older women I am assured, he said, by t Minister of Labour that there is no present intention of cal them up for selection interview within the age groups cov by the Registration for Employment Order

Return of Tuberculous Soldiers

Mr T E Groves asked the Secretary of State for Wa he was aware that orders had been issued by his departm for 40 tuberculous military cases in the Addington Hos for Natal, and 120 similar cases at Oribi, to be returned to th country, and whether he would state the arrangeme made for the reception, distribution and maintenance these cases when they arrived in this country —Capt H D R Margesson replied No special instructions hav been issued by the War Office regarding these cases, and I presume that Mr Groves refers to general instructio regarding the return to this country from South Africa o soldiers suffering from tuberculosis On arrival in t country soldiers suffering from tuberculosis are sent to military hospital where they receive treatment as nece ssa until they are handed over to the care of the local hea authority

Coroners in England and Wales

Replying to Dr Russell Thomas, Mr Herbert Morri said There are 297 coroners in England and Wales of who according to my present information, 13 are employed or full-time basis Several coroners occupy more than rship, the total number of coronerships being 333 ggregate salaries of all coroners for 1939 amount to)7, and the expenses incurred by them in the execution ir duty to £145,666

Pensions for the Blind

ROBERT YOUNG asked the Minister of Health whether as satisfied that the purpose for which the pensionable f a blind person was reduced from 50 to 40 had been ed or whether his attention had been called to the extent hich local authorities had caused the financial benefits of mended act to be reduced or cancelled, and what steps roposed to take to give to eligible blind persons the fit intended for them —Mr BROWN replied It was ys contemplated that a local authority in granting finan- assistance to a blind person under the Blind Persons Acts ld take into account the amount of any old age pension ved by him, and one of the objects of reducing the ionable age for blind persons was to secure that the len of providing assistance to blind persons should be ed between the Exchequer and the local authorities

Exemption from Billeting

r E H KEELING asked the Minister whether he was re that a large proportion of the householders in Harrogate *n whom evacuees had been billeted had submitted* lical certificates recommending that they be taken off the ting list, and whether such certificates were being pted —Mr BROWN replied I am aware that a number ouseholders in this district have submitted medical certifi- s to support a claim to be relieved of the responsibility accommodating billeted persons In such cases the seholder is informed that he has the right of appeal to the l tribunal set up under the Defence (Billeting Tribunal) les, 1939, and it is for the tribunal to decide whether exemp- from the acceptance of billeted persons should be granted

Public Health

From the School Reports

NOTTINGHAM

THE medical inspection subcommittee of Nottingham's ucation committee in 1940 consisted of eight members, o of whom, the chairman and one woman councillor, doctors The staff consists of Dr Arthur Newth, nior medical officer for education, Dr R G Sprenger, nior assistant, 4 other full-time assistants, 7 part-time ecialists, 7 dentists, then there are a part-time ychiatrist, 2 educational psychologists, a speech- erapist and a social worker attached to the child- idance centre, and finally 8 nurses and a full comple- ent of clinical assistants, dental attendants and clerks ese attend to the medical needs *of the 36,000 school-* ildren of the city In connexion with the evacuation eme a survey of the children made it possible to test e completeness or otherwise of the record of defective ildren Beyond some bed-wetters and children with haviour troubles, few defectives were found who were t already known "A large number of cases were ported as having some serious condition such as heart kidney disease or tuberculosis which was found not be present when the child was last examined This pports the idea that the avoidance of invalidism is a t unimportant function of the school medical service " is of course possible that some of these chronic invalids" had developed serious disease since their t examination, but presumably the passage means that ey had not done so Generally a survey of children sent from school for long periods reveals that the great ajority are not suffering from any disease to warrant eir non-attendance, a few are found with lesions which ake them suitable for special education which it is the ty of all education authorities to supply, and the mainder, an extremely small number, are either dying incapable of survival beyond the school-leaving age e number of children whose lives are wrecked because mebody has detected an *innocent* heart murmur or buminuria greatly exceeds that of those destroyed by sease This is one of the major truths of the school edical service

Dr Newth, in discussing the increase of scabies, which ottingham shared with most parts of the country calls that in the last war there was a similar increase ten associated with the return of a soldier on leave, but the present epidemic started before the war, even before conscription, and the incidence of scabies in those serving in the Forces in this war has not been severe He says that scabies occurs chiefly among unclean people, but the connexion is not direct, scabies infection is, in fact, very common in clean people, but in them the mite is soon dislodged, so we very rarely see anything more than a deserted burrow except in the dirty In contrast to scabies, body lice are rarely found in school-children, even those of the dirtiest and most neglected families "Towards the end of 1940 one began to notice a deterioration of the clothing of some of the children," but their nutrition was maintained at an excellent level Dr Newth says he cannot understand the mentality on the part of a mother "who, having made the brave decision to send her child overseas, withdrew her application when she was told that dental treatment was essential"

SMETHWICK

Dr Hugh Paul says that the outstanding feature of the year was the continuing high standard of physical and mental health which was maintained throughout "Even the sustained night bombing of the last quarter failed to have any visible adverse effect on the children" It seems likely that the unprecedented high level of health and nutrition which we reached before the outbreak of war largely accounts for the comparatively slight effect air-raids have had on the health and morale of our people If so, it means that in the end the butter will beat the guns

Among 8254 school-children of Smethwick, 74 were in 1940 referred to the chest clinic for suspected or possible tuberculosis Of these, one was found to have definite pulmonary tuberculosis and one another form of the disease, 61 were excluded as not tuberculosis, and 11 were suspected of possible pulmonary tuberculosis Suspected pulmonary tuberculosis in children and adolescents is one of the most difficult medical problems of the present day To make a positive or negative diagnosis where this cannot be better than a guess may easily be disastrous, for if it is wrong it must lead either to unjustified invalidism or to the loss of opportunity to avert a fatal disease How to keep a suspect under supervision without creating invalidism is a problem medicine has not yet solved, yet in theory it is easy and the most useful work that a physician can do

KENT

In the second half of 1940 Kent became a battlefield, so what had been a reception area had many shifts in school population The part of Kent which for education is administered by the county remained in the main a reception area, but the coastal towns which are their own education authorities had many vicissitudes, with the result on the county that though the school population remained fairly constant in numbers, it was much disturbed Moreover, the county was subject to repeated air-raid warnings, so the children passed much of their time in shelter conditions Yet, from Dr J W Fox's report, presented by Dr Constant Ponder, the children's health and spirits did not suffer appreciably, and from the school medical statistics of the year it would not be possible to tell that anything unusual had happened Dr Fox gives a brief but most interesting note on the improvement in nutrition of evacuees as measured in terms of growth This is striking and widespread, and is not wholly explained by the change from town to country life "The evacuees compare favourably with native children Perhaps the same can be said where Kent children have gone" Change, in itself, seems to be favourable and Dr Fox suggests as a permanent feature of education periodic exchanges of children from one district to another

The Kent dental scheme does not yet make general provision for the treatment of pupils in secondary schools but this is available *to some extent* The senior school dentist in his report remarks that in some schools the parents though unable to afford private dental treatment do not take advantage of the clinics with results that are deplorable "Many of the pupils at these schools present an appalling amount of gross oral sepsis" He attributes this refusal to accept treatment to "a curious form of snobbery, either on the part of the parents or, more frequently, of the children themselves"

From the Annual Reports

CORK STREET FEVER HOSPITAL, DUBLIN

Dr C J McSweeney's report for 1940 is written on a general note of optimism Amongst 2160 patients treated (a record figure) there was a gross mortality of 5 5%, the lowest ever recorded in the history of the hospital Gravis diphtheria is apparently still prevalent in Dublin but the fatality (6 5%) shows a slight improvement from the previous year, although clinically the cases appeared to be more severe This success is attributed partly to the use of "avid" diphtheria antitoxin in certain severe cases, an experiment which has been recorded already in these columns (McSweeney, C J *Lancet*, 1941, 1, 208) Whether one agrees or not with this conclusion, further elucidation and trial of the elusive "anti-B" factor in diphtheria antitoxin remains a matter of impelling interest Nine cases of diphtheritic respiratory paralysis treated in a Bragg-Paul pulsator did well, but Dr McSweeney seems hardly justified in asserting that the 48 patients whose recovery has been credited to this machine since 1935 would inevitably have died without mechanical aid to respiration Streptococcal diseases fared well during the year, there being a trifling mortality (0 87%) in scarlet fever, one death in 20 cases of puerperal sepsis and no death at all amongst 78 cases of erysipelas Dr McSweeney does well to remind us how much the modern treatment of erysipelas owes to chemotherapy Chemotherapy in combination with specific serum was used in the treatment of 30 cases of meningococcal meningitis and 28 recovered, a result for a small series which could scarcely show improvement Nor could a fatality of 1 83% for 109 cases of lobar pneumonia treated with sulphapyridine and specific serum Bronchopneumonia alone or in combination with measles or whooping-cough fared less well Indeed a curiously high fatality of 21 8% in whooping-cough appears almost wholly to have been due to bronchopneumonia, no less than 64 out of the 94 cases treated being so affected

DUBLIN'S HEALTH —In an address to a conference of municipal authorities Dr M J Russell, superintendent M O H for Dublin, said that the extension of the city boundaries during the last twenty-five years has increased its area from 7911 acres to 18,777 and its population from 312,750 to 491,800 The density of population has thus been reduced from 38 8 persons per acre to 26 per acre The death-rate per 1000 in 1915 was 21 8, last year it was 14 5 The death rate from tuberculosis had fallen by more than half Credit for the progress in the prevention of tuberculosis, and improvement in general health, was in part due to better housing and wages, and a purer milk supply Dr Russell advocated a system of differential rentals which would discriminate in favour of the tuberculous

Infectious Disease in England and Wales

WEEK ENDED OCT 4

Notifications —The following cases of infectious disease were notified during the week smallpox 0, scarlet fever, 1217, whooping-cough, 2078, diphtheria, 997, paratyphoid, 87, typhoid, 34, measles (excluding rubella), 715, pneumonia (primary or influenzal), 629, puerperal pyrexia, 151, cerebrospinal fever, 109, poliomyelitis, 31, polio-encephalitis, 2, encephalitis lethargica, 4, dysentery, 108, ophthalmia neonatorum, 80, relapsing fever, 1 No case of cholera, plague or typhus fever was notified during the week

Deaths —In 126 great towns there were no deaths from measles, 4 (1) from enteric fever, 1 (0) from scarlet fever, 11 (0) from whooping-cough, 26 (3) from diphtheria, 33 (0) from diarrhœa and enteritis under 2 years, and 14 (0) from influenza The figures in parentheses are those for London itself

Birmingham, Wolverhampton and Poole each reported a fatal case of enteric fever There were 3 deaths from diphtheria at Gateshead In the same week Dublin had 45 deaths from diarrhœa

The number of stillbirths notified during the week was 204 (corresponding to a rate of 40 per thousand total births), including 16 in London

Letters to the Editor

THE CHRISTMAS GIFT

SIR,—Old customs and traditions are greatly and treasured by elderly people Memories of p are very precious—perhaps none more so than t happy Christmas days gone by For many years readers have most generously supported my ap behalf of the christmas gifts fund of the Royal M Benevolent Fund and the annual distribution of a 30*s* has brought great happiness to our benefic many of whom are old and lonely I have now president of the fund for nearly 25 years and would to thank all who have responded to my appeal in years and have every confidence that this year the kindness will be shown With an additional cont tion we could raise our gift this year to £2 instead of which would give much pleasure

Will contributors please address to "Christmas Gift Royal Medical Benevolent Fund, 1, Balliol House Manor Fields, London, S W 15, and their gifts will all gratefully acknowledged

THOS BARLOW,
President, R M B F

ENURESIS

SIR,—Mr Winsbury-White (*Lancet*, Sept 20, p 331 has analysed 310 cases of enuresis in an age group, I gather, of 2–14 years He finds that in 98% there was a history of at least one of the exanthemata The signific ance of this figure is not explained, and I was furthe mystified when I found that the exanthemata "did not always precede the enuresis" One is reminded of the American surgeon who reported that over 90% of the married women on whom he operated for acute appendi citis had husbands who were cigarette smokers

Mr Winsbury-White has also made numerous observa tions on the normal calibre of the urethra at various ages, by noting the size of the largest instrument which will lie in the urethra without being gripped Is the passage of sounds into the urethras of normal childre of both sexes a psychologically justifiable procedure He found, in 70% of these patients on whom he performed cystoscopy, inflammation of the trigone and the internal urinary meatus, and in 76% of those in whom the po terior urethra was examined, inflammation of this t "Several cases with chronic coliform infection had much dilatation in the upper urinary tract that t infection was obviously a complication of urina stasis," but of the cases examined by urography "Cu showed abnormalities in the upper urinary tract wh though slight, indicated early changes due to the chro inflammatory process below" It would be interesti to know how he differentiates these apparently oppo groups He adds, "Where the dilatation was withe remedy so was the infection" In the light of the rec work of Helmholz and others at the Mayo Clinic, I would like to know what methods of treatment we tried before the infection was finally regarded as withe remedy

Lastly, he states that "the paraurethral gland of Skene and any glands (except those of Bartholin) which open directly into the urethra are the homologues of the glands of the prostate" The glands of Bartholin do n open into the urethra, but lateral to the hymen bet its attached border and the labia minora The homolo of the prostate is a more complex business than statement suggests, but in any case the next p ("and an infection of the vulval glands automatic involves the urethral glands") appears to be a n sequitur

His observations, and the treatment that follo rationally from them, are of such importance that th deserve discussion I want especially the pædiatrists to me whether the 97% who received benefit from uret dilatation might not have been cured by the threat t "next time you do it, you'll have those things sho up you again" Perhaps the 3% who obtained no ben rather enjoyed the process

Whitchurch, Aylesbury RAYMOND GREENE

SIR,—In 1918 I published a study on enuresis based several thousand cases of all ages and I may therefore cl to be familiar with this disease Mr Winsbury W ns to be under the impression, that an inflam-ion of the lower urinary tract is in most cases sally connected with enuresis He does not mention many other causes which produce this symptom—example, the disturbance of the nervous control of detrusor and sphincter muscles of the bladder, spina da occulta, epilepsy idiocy, threadworm infection, inism, and in a certain number of cases simple lazi-s and indifference There are also large numbers of ents of all ages in whom none of these causes can found, and who form the group of " enuresis sui neris " These patients have insufficient tone in the incter muscle and defective nervous conduction tween bladder, spinal cord and brain The contrac-ns of the detrusor muscle under the influence of the l bladder are not considerable enough to wake the tient Those cases in which every other form of eatment—whether by suggestion, drugs or instruments had failed I treat with 3–4 epidural (sacral) injections 30 c cm of saline, achieving immediate success in % and ultimate success in 68% The injection causes mechanical irritation of the lowest part of the spinal rd with its nerves to the bladder and the sexual gans In men, priapism lasting several hours is often used, and if cystoscopy is performed shortly after the jection hyperæmia of the lower half of the bladder hich did not exist before is found in most cases The tients feel the need to micturate more imperatively, d this wakes them up before they have passed urine asting success I believe to depend on a kind of education the bladder, comparable to the training of bowel tion Diet is also important as my cases fell to a quarter the number when the fat deficiency of the last war was lieved in 1919 by the arrival in Germany of bacon om America I agree with Mr Winsbury-White that yperæmia and chronic inflammation of the trigone and e neck of the bladder are common in adult women, and published two papers on this as a cause of frequent icturition in 1905 and 1906, but I have generally und no evidence of such inflammation in children, ith or without enuresis Might not the hyperæmia e caused by the instruments inserted ? The absence every microscopic sign of infection in the urine of 5% of his cases seems to suggest this explanation, since real inflammation of the neck or the trigone of the-ladder a few leucocytes are always to be found

ARNOLD HEYMANN,

Bensham General Hospital, Gateshead

Late Consultant Urologist at Luisen-spital, Dusseldorf

BIPP AND ITS FRIENDS

SIR,—I was very pleased to see your leader on the se of bipp for to many of us who have used it in housands of cases in this war and the last it still remains he treatment of choice One great advantage, which ou do not mention, is the ease and painlessness of the ressings , a man who is desperately ill and septic cannot tand the pain of removing a dressing that is sticking adly, or, on the other hand, a daily anæsthetic This nakes the treatment highly popular with the patient imself , he can eat his dinner after his dressing and there s not that rise of temperature due to opening up resh paths of infection which must occur when the emoval of the dressing causes bleeding from the granu-ating area Any pus can escape quite easily between he wound and the gauze well " buttered " with bipp f after excision of the wound, designed to leave as far as racticable a funnel-shaped cavity, a bipp-covered plug f gauze is carried lightly to the bottom of the wound, o dressing need be done as a rule for 2 or 3 days The lug is then removed and never replaced , the oily layer eft in the track will keep it well open and allow free rainage It will rarely be found necessary to reopen he wound and in many cases it is possible to do a econdary suture in 7–10 days

The bogy of bismuth poisoning is easily laid I first eard of bipp when on leave from France in the last war, efore, I think, any account of it had been published Either my informant got the formula wrong or my emory luckily let me down and our bipp was made from ismuth carbonate 2 parts and iodoform 1 part There s no reason whatever to use the nitrate, which is well nown to have dangerous properties , the carbonate is bsolutely safe and as much as 6 oz used to be given for bismuth meals before barium came into its own I have seen trouble from Morison's formula but never from the carbonate, while the lessened amount of iodoform also precludes any risk of iodoform poisoning, which did occasionally occur During this war we have added 10% of sulphonamide powder and so greatly increased its value Bipp used with bismuth carbonate is safe, effective and will please both surgeon and patient I hope it will at least be given a trial by any surgeon who has not used it

Southampton

H JOHN NIGHTINGALE

HOME GUARD PROBLEMS

SIR,—The views lately expressed on medical arrangements in case of invasion diverge on minor details of organisation and equipment needed but all are fairly unanimous about the existing position Most correspondents agree that the arrangements made are totally inadequate that the equipment issued is rudimentary , and that the little preparation that has been made is unsuitable to meet the conditions that can reasonably be expected during an attempted invasion

It is six years since the shadow of war was first discernible in England (the A R P Department of the Home Office was established in 1935) It is three years since every intelligent Englishman was convinced that war would have to be waged to stop German aggression and that all civil defence measures must be pushed to the utmost It is over two years since the outbreak of war and it is more than a year since we were told that invasion should be expected at any time After all this, suddenly to discover that our casualty arrangements made for invasion are practically non-existent can only lead to one of two conclusions Either the criticisms levelled have no basis of reality and are therefore extremely harmful to morale, or responsible officials have been guilty of an oversight or lack of efficiency The articles and letters calling attention to the lack of preparations are written by doctors engaged in Home Guard, civil defence and so on, who are therefore specialists in their fields with the facts at their disposal One may quarrel with their conclusions but the picture they paint looks accurate Are the arrangements which they think necessary in fact essential, and if so was it humanly possible to make the necessary provision before this ?

Casualty services, besides their humanitarian aspect, have a direct military value for they are essential to the sustenance of morale It is questionable whether successful defence can for long be carried on if the medical service has broken down At times soldiers may have to be asked to fight to the bitter end, even without a casualty service, and they will do this if they understand the reason why and do not feel that the lack arises from inefficiency on the part of those responsible for their welfare In England where successful defence is so inextricably mixed up with proper morale the need for proper medical arrangements is vital for security reasons

Was it, however, possible to make those arrangements ? It can be argued that we had to expend our maximum effort on munitions production, fortifications and military training This may be so, but even the manufacture of a million tanks and 24 hours a day training need not have prevented doctors and administrative officers pushing on their preparations to the utmost, for these are independent of the others It may be said that medical services do not depend only on medical men and organisation, but that precious equipment is also needed and this could not be manufactured because of other calls on the factories But A R P and E M S preparations were based on estimates and sustained casualty figures which were incomparably greater than any met so far or likely to be met for a long time to come Equipment, then, has been prepared for all the casualties we may get, the only objection being that all our organisations and equipment are concentrated in the industrial areas, whereas Home Guard casualties will mainly occur in rural areas It seems to have been forgotten that the Home Guard are our own civilians who have taken up the rifle in defence of their homes As soon as it became apparent that the threat of invasion was changing the tactical picture of defence plans should have been reviewed and necessary steps taken to regroup our dispositions and redistribute our equipment Both personnel and equipment are there, but bureaucracy and lack of foresight have prevented their being put where the danger is most likely to occur and made flexible enough to meet the new offensive strategy The successes of the Nazis have come from their speed and unexpectedness Our defence must be planned with this fact in mind

Whose responsibility was it to make those arrangements? The Ministries of Home Security and of Health could perhaps have claimed that the Home Guard being military falls properly within the province of the R A M C This would be a short-sighted view, for the R A M C is but a limb of the Army, and the Army will always remain mobile, it may at any time again become an expeditionary force. The Home Guard was built to meet a need the Army could not meet, except at the risk of undue dispersal It always remains static within its township and its casualties will be inextricably mixed with those of the civilian population It must therefore remain a medical responsibility of the E M S at any rate until the War Office decides to take over the whole civil defence of the country

The Prime Minister said in his recent speech at County Hall that he is advised that our civilian preparations are being pushed to the utmost, that as a result of experience changes have been made and everything possible is being done Can we have overlooked the medical arrangements in case of invasion?

Battersea G B SHIRLAW

SIR,—In your issue of Oct 11 (p 442) Brigadier Cowell turns his guns, wanton and unprovoked, on the Home Guard Medical Service, which has distressed him by using the expression C C P (casualty collecting posts) to describe the posts which it arranges for the reception of its own casualties Being to some extent responsible for that term I join issue with him at once Practical experience of conferences with the civil authorities shows that they do not understand the nature of military posts unless those posts which are really distinguished in equipment, control and function are also distinguished by different names. The civil authorities meet with exactly the same difficulty when dealing with the military, most of whom are unaware of the essential differences between a first-aid point and a first-aid post In vain does Brigadier Cowell proclaim that the initials C C P are "confusing, redundant and unnecessary" So long as he requires three separate sets of initials to describe his own regimental posts—F A P, C A P and even P A P (platoon aid post)—he is in no position to rage about the mote in his brother's eye

GORDON WARD,
Sevenoaks Lieut-Colonel, H G

PLUMP TYPE OF GRAVES'S DISEASE

SIR,—The paper under this title by Dr Trotter and Mr Eden in your issue of Sept 20 I feel calls for some comment, since it results in making certain generalisations which are scarcely justified by the evidence Familiarity with toxic goitre in all its many manifestations teaches that there is no classical sign of the clinical complex described by Graves which may not be absent, and it is dangerous to make any attempt to separate off any particular category as being fundamentally different from the rest The medical officers who have worked in recent years at the L C C thyroid clinic at New End have been familiar with the toxic patient who has not lost weight or may even have gained Among several hundred patients treated by partial thyroidectomy there have been many more "plump" individuals than are recorded by Dr Trotter and Mr Eden, yet I do not recall that any deaths have taken place among them As pointed out by Dr Page in your issue of Sept 27, death in these particular instances may have been due to some cause quite unconnected with the type of patient, and it seems to me to be entirely misleading to make a general statement that the type entails special dangers on evidence derived from so small a number Lymphoid hyperplasia is common in all types of toxic goitre

In addition to this it is, in my opinion, misleading to suggest that the results of thyroidectomy are likely to be uniformly worse in the "plump type" than among other patients It is well known that the results are, in general, much less dramatic among the "atypical categories (including the plump patients) than the classical examples of "Graves's disease" and is room for judgment in forming an opinion for or a operation Nevertheless the more slowly obt benefits are usually well worth having in the run, and the delay is no argument for withho treatment

If I were to apply the principles of generalisation by the writers of the article I might maliciously out that among their seventy patients the mortality been more than four times as high as it ought to ha been Let the causes for this be fully investigated, I should anticipate that this mortality will not b repeated when the numbers treated in their clinic hav materially grown

Wendover GEOFFREY KEYNE

NATIONAL HEALTH ASSOCIATION

SIR,—I should like to bring to the notice of your readers the objects of the National Health Association, formed on Aug 22 at Tunbridge Wells It must be evident to the profession that big changes in medical and hospital practice will come about after the war, more especially since the Minister of Health has said that voluntary hospitals will receive aid from local authorities At the second reading of the National Health Insurance, Contributary Pensions and Workmen's Compensation Bill in July many Members of Parliament expressed their strong disapproval of the medical benefits allowed to insured persons, and also of the lack of diagnostic and treatment facilities in insurance practice The National Health Association was formed so that the public and medical profession could get together and solve, without interference from outside sources, such as vested interests and political parties, the problems that affect their common interest

When the National Health Insurance Act was passed in 1911 doctors and the public became conscious of medical politics, or of the interest that the state was now going to take in the administration of medical benefits and the profession This state interference forced medical men to find a refuge from the Government and the politician in the B M A and the Medical Practitioners Union, but even after 30 years little or nothing has been accomplished for either the profession or the public For obvious reasons the profession was not represented in the House of Commons as a political entity, and, except for a small number of doctors representing their respective parties, legislation from a purely medical viewpoint and also that of the sick man was impossible to implement A square deal for the doctor and the patient was almost impossible, leaving the question of the remuneration of the profession in its present state and no special facilities available to the public, other than through the already overworked voluntary hospitals Thus the whole subject of specialist medical benefits and remuneration in N H I practice was left to the B M A and the M P U to adjust, which they have not yet been able to do This I feel has been due to the fact that they deal directly with the Ministry of Health, an administrative body, and not with a legislative chamb Parliament alone can solve this problem and the objects of the National Health Association are to educate the public and Members of Parliament in what the doctor and people desire and thus get legislation passed that i acceptable to all concerned The association will make it possible for doctor and patient to sit round a table and discuss problems affecting on the one hand the economi position of the profession and on the other modern diagnostic and treatment facilities, clinics and hospital which come within the scope of post-war reconstruction It is hoped that, by means of properly directed propaganda, controlled by the profession and the public, the association will be able to influence public and parliamentary opinion, thus obtaining through Parliament a modern and efficient national medical service that is acceptable to all The association is meeting with support throughout the country and although only a newborn child is rapidly expanding I should be pleased to send a copy of its memorandum to any interested reader

E F ST JOHN LYBURN

Hastings Clinic, Ferndale, Tunbridge Wells

LIGHTING OF WARDS

—After the war many hospitals will be remodelling vards and the experience at the Moreton District al may help in designing lighting systems This al built two new wards in 1935 and for general ig individual bed lights with additional central ig was adopted ; this is very satisfactory but care l be taken to fit the individual bed lights sufficiently on the wall so that they cannot be smashed by a attached to the bed For lighting during the night iatron, Miss M B Ockenden suggested that the should be lit by concealed lights such as are used on tairs and corridors of cinemas, and this idea was ed A fitting, the "Major Flush Louvre Light" nfactured by Manjor Equipment Co), was let into all where it would be underneath a bed, 1 ft 8 in. the floor At this height the louvred openings are below the level of the bed and the light cannot be tly seen by any patient in the ward , at the same they illuminate the polished floor completely and eflected light makes objects on the beds and lockers visible This fitting could be improved, for the cement of burnt-out bulbs is troublesome and the st power of bulb available is 15 watts, which is too

Five of these were fitted in a ward of 12 beds . 6 in × 20 ft and gave more light than is required , ight to 300 sq ft should be sufficient This system ghting has since been copied in the Acland Nursing ie and the Nuffield wards of the Radcliffe Infirmary xford

OIL FOR FLOORS

R,—We were interested to read Dr J M Twort's r of Aug 16 (p 205) in which he pointed out the inogenic properties of spindle oil, and the danger h may therefore be associated with its use as a dust-r on hospital floors The term "spindle oil" is used over a wide variety of mineral oils of varying degrees finement, ranging from the relatively crude, carcino-c lubricants employed in cotton mills to the highly ied, biologically inert white oils and the new paraffi-liquidum leve B P Cost is a useful indication of degree of refinement of these oils, the more highly fied oils costing 2*s* 6*d* per gallon while the cruder may be obtained for less than half this amount extent of the danger of using "spindle oil" as a layer depends on the degree of refinement of the ised and the frequency with which it is applied to s, so that care is necessary in selecting an appropriate

We have always used a well-refined oil of the more ensive type, the specifications of which we have ned (*Lancet*, 1941, 2, 123) Dr Twort informs us this oil is unlikely to be harmful, and we consider, efore, that the danger associated with the application presence of spindle oils of this nature on hospital s is negligible Should circumstances necessitate olonged and intimate contact of the skin with the oil re and after it is applied to the floors the still more ly refined oils may equally well be used These oils equally efficient dust-layers, but are slightly more ensive that the spindle oil we have used Dr Twort kindly tested such an oil for us (Technical White Oil ied by the Manchester Oil Refinery, Ltd.) and found be biologically inert It was the consideration of carcinogenic properties of the cruder oils which led o recommend the more highly purified oils for dust-ng on bedclothes, where intimate contact between the ent's skin and the oil is inevitable

tional Institute for Medical Research

THE GOVERNMENT AND PROPRIETARY MEDICINES

IR,—At the recent annual general meeting of Beechams , Ltd , the Chairman said (as reported in the *Times*)

For the ninth successive year our trading profits show an ease The profit for the year amounts to £1,085,893 The company s normal trade both at home and overseas, out accounting for Government contracts, shows con-rable expansion

"Since we last met, Parliament has passed the Pharmacy and Medicines Act of 1941 . Generally, it is hoped that the new Act will improve the status of proprietary articles and patent medicines The directors have decided that the full benefit shall be given to the public "

As regards the Government contracts mentioned, the Financial Secretary to the Treasury, in reply to Sir E Graham Little, M P , said on Sept 30 "So far as I have been able to ascertain, no Government department has a contract with this firm " I think the profession is entitled to know which of these two statements is correct

RADIOLOGY AS A CAREER

SIR —It is with surprise that I read of the novel scheme for producing radiologists, revealed in your annotation of Oct 11 (p 432) It is difficult to appreciate the reason for the unusual step that is being taken, unless a shortage of radiologists is upon us At present there is no evidence that such is the case I have recently been informed that no radiologists are required by the E M S , and as the Services will not take them without considerable clinical and radiological experience, the new candidates will not find their path as rosy as would appear at first sight In any case it seems a retrograde step to be subsidising would-be specialists when, to my knowledge alone three qualified radiologists are unable to find work. Radiologists have many trials to undergo because their specialty is a junior one, but I am surprised that my senior colleagues have not resisted this unnecessary attempt to induce people to join their ranks, for it cannot enhance our prestige

D M R E

HAD THE CERTIFYING DOCTOR KNOWN

SIR,—At a recent gathering of doctors at a steel works the topic of certification of employees in industry came under discussion, and the company had received an urgent request for help to manufacture a part for a war machine The shortage of this component was causing a serious delay in supplies It so happened that there was in one shop adaptable equipment but no skilled operatives available In reviewing the labour force it was remembered that three men who were skilled at this type of work had been transferred several years before when orders were short to other departments They were requested to report back the following week to their original shop Two days later they presented medical certificates, each bearing a different doctor's signature, giving some reason for their not transferring to the operation required I felt satisfied that the real cause of the trouble was not a question of health The men had settled down to a new occupation with a fresh set of men, in surroundings which happened to be more congenial, and they were displaying the understandable and common dislike of being uprooted and disturbed I interviewed the three men and they all seemed to be in normal health I pointed out to them that, although the work that they were at present doing was of importance, the work to which they were requested to transfer was particularly urgent and vital and that their greatest utility value to the country on this occasion would be to return to their original occupation Two of them, on considering these points immediately volunteered to do as we wished The third man disclosed that he had lost a sister and brother from tuberculosis and that as the original shop was certainly dustier than his present shop he did not want to return It was apparent that his fear was quite genuine It was, however, pointed out to him that if he had a liability to tuberculosis probably the shop that he was working in was not the most suitable that open-air work would be preferable, and that in any event he ought to have enough courage to have an examination before it was too late for his doctor to help him To this he reluctantly agreed and it was arranged that he should be examined by the local tuberculosis officer The result of this examination was not reported, but ten days later the man presented himself for work in the occupation that he had been requested to take up and he was a happier man than he had been for some years past

That is what happened ; but if this satisfactory conclusion had not been reached the problem would have been different Even supposing twelve able-bodied men from the Ministry of Labour had been available—which was out of the question—it would have been fortunate if as many as three of them could have adapted themselves to the work, which calls for considerable dexterity and stamina, and those three men would have taken at least two or three months before they could have given the output that the original three men actually gave in a few days I was urged to pass these particulars on to you I do so, with some reluctance and with the feeling that had the certifying doctors known all the facts the situation would never have arisen It is, however, worth considering how such events can best be avoided

WORKS MANAGER

Obituary

JAMES KERR

M D CAMB , D P H

BY the death in Edinburgh on Oct 5 of Dr James Kerr in his 80th year the country has lost its Grand Old Man of school hygiene It was in Bradford that he initiated what was to become a vast instrument of human welfare, and when the B M A met there in 1924 the president described him as "a brilliant scholar who never realised how brilliant he was even when it was impressed upon him by others" But for his epitaph he would have chosen "the first school medical officer for London"

James Kerr was born in Glasgow, educated at Manchester Grammar School St John's College, Cambridge (of which he became a fellow) and St Bartholomew's Hospital, qualifying in 1887 He took up the double specialties of eye and ear surgery and after hospital experience at Swansea and elsewhere he started practice in Bradford The school board of this town (Margaret McMillan was then a member of it) was the most progressive in the country and employed Kerr as consulting medical officer He was thus the first medical man in England (with the possible exception of Clement Dukes) to pay attention to the physiological questions arising out of the practice of confining children within walls and seated at desks during long periods each day during a time of their life which should naturally be spent largely in activity in the open air His investigations produced new and vital knowledge of the reactions of children to these artificial conditions and paved the way for the advances in school practice which took place in the first two decades of the century The fruit of these early researches was published by the Royal Statistical Society, which awarded him the Howard medal, and in the Ingleby lectures delivered at the University of Birmingham

In 1902 the school board for London, alarmed at the evidence of widespread defect among the elementary-school population, determined to create a medical department and Kerr was appointed as its head He thus became the first whole-time school medical officer in the country and he made full use of the opportunity thus created He possessed exceptional powers of leadership and gathered around himself a band of brilliant young specialists whom he fired with his own enthusiasm His conception of school hygiene was broad and inclusive, medical inspection and treatment, with which the idea became linked in many minds, was for him far too narrow an interpretation He thought in terms of the whole child and of its primary requirements, physical and mental, for a healthy life. His mind worked always as an educationist, rather than as an officer of the public health concerned primarily with the prevention of disease, and he had a keen understanding of the social implications of his work Thus he created a school nursing service, started the open-air school movement, and engineered a series of reforms in educational methods Slates and pencils disappeared, fine work in infants' departments was abolished sewing by artificial light prohibited, sight-saving classes established, and personal cleanliness insisted upon And on the work done in London under his direction were based the legislative enactments which later established the school medical service throughout the country In 1911 the London County Council, which had superseded the school board as education authority, decided gamate under one head all the medical services direction and Sir William Hamer thereupon school medical officer Henceforward until his ment in 1926 Kerr occupied the post of research officer to the council and was freed from the t office routine He was then able to devote much time to literary work. He re-wrote New "School Hygiene," the standard textbook on the ject, his life-long interest in the hygiene of the senses found expression in a monograph on " Vision and the Myopic Scholar", and finally he lished "The Fundamentals of School Health," a packed with concise information and revealing the lines some of the idealist's dreams of the future.

After his retirement, spent in Edinburgh, interest in school hygiene never flagged and masterly reviews came from his pen His mind re acute and active to the end During later years he tified himself with the care of the deaf in S becoming chairman of Donaldson's Hospital He survived by his wife and his son, Dr Douglas principal police surgeon to Edinburgh Corporation.

ARTHUR CHARLES SHELFORD

M.B EDIN ; SURGEON LIEUTENANT, R N V R.

Arthur Shelford was born in 1914 at the D School, Alnwick, where he also received his early ed tion In 1932 he began his medical studies at Edin University and he graduated M B in 1937 holding resident posts at Sunderland Infirmary he joi the practice of one of his chiefs who writes of him "Shelford was rather shy but the more one knew him the more one liked and respected him He had sound principles of conduct and the character and will power to put them into practice Conscientious and interested in his work he would have made an excellent practitioner, and many of his patients still talk to me about him He was devoted to his home, Northumberland and the Cheviots" Dr Shelford volunteered for the Navy at the outbreak of war and received his commission as a surgeon lieutenant at the end of 1939 Early the next year he was posted to H M S *Express*, and during the week of the Dunkirk evac He had some strenuous and exciting experiences He reported lost in September, 1940, and in July of th the German authorities notified the Admiralty th was buried on the island of Pellworm on Sept 26, 1

dico-Legal Society

meeting of this society will be held at 26, Portland Place, don, W 1, on Thursday, Oct 23, at 4 30 P M, when Dr mas Christie, medical officer of Winchester Prison, read a paper on the manic depressive psychoses in relation he crime of murder

ority Milk

he Ministry of Food will allow priority claims on the ply of liquid milk up to two pints a day for periods mally not exceeding one month by the following people

) Workers including domestic workers, during an illness which porarily incapacitates them for work

) Persons suffering from an illness characterised by high and longed fever or from post-operative conditions after major rations

) Sick children not attending school

) Persons suffering from one or more of the following illnesses, ether incapacitated or not Active tuberculosis of all types, osis affection of the mouth throat or gullet or organic nervous order causing interference with swallowing, gastric duodenal or stomotic ulcer, certain cases of dyspepsia due to conditions er than ulceration of the stomach or duodenum colitis, diabetes llitus thyrotoxicosis; nephritis

) Expectant mothers who are allowed a priority claim of one t a day until approximately one month after confinement

A certificate signed by a medical practitioner will be uired, except by an expectant mother, for whom the tificate of a certified midwife or health visitor will be epted

Infants between one and twelve months old who are being tle fed on cow's liquid milk will be supplied with up to ints a week, in addition to their priority entitlement of 7 ts a week under the milk supply scheme The additional antities must be bought at the full retail price

Memorial to St Thomas's Masseuses

A war memorial fund is being formed in memory of the four staff masseuses who lost their lives when St Thomas's Hospital was bombed in September, 1940 It is suggested that funds for four bursaries should be raised to help students in the physiotherapy department, to be awarded as follows

In memory of Barbara Mortimer Thomas—primarily for a student from the Dominions

In memory of Gwendolen Lockyer—primarily for the daughter of a medical practitioner

In memory of Marguerite Doucet—primarily for the daughter of a past or present member of the Services

In memory of Stephanie Dunn—primarily for the daughter of a clergyman

Donations should be sent to Miss M Randell, at the massage department of St Thomas's Hospital, S E 1

Lister Medal

The Lister medal for 1942, which is awarded in recognition of distinguished contributions to surgical science, has been granted to Prof Evarts A Graham, professor of surgery in the Washington University (St Louis, Mo), and he will deliver the Lister memorial lecture in 1942, or later, under the auspices of the Royal College of Surgeons of England

Royal Society of Medicine

On Tuesday, Oct 21, at 2 30 P M at the section of comparative medicine Mr H W Steele-Bodger, M R C V S, will open the first of a series of discussions on the general principles involved in a campaign to control diseases of cattle inimical to man At 5 P M on the same day there will be a general meeting of fellows, and on Thursday, Oct 23, at 4 P M, the section of urology will hold a clinico-pathological meeting On Friday, Oct 24, at 2 30 P M, Dr Donald Paterson, Dr Richard Dobbs, Sir Lancelot Barrington-Ward and Mr David Levi will open a discussion at the section of disease in children on pyloric stenosis in infants At 3 P M on the same day Dr E H R Harries will deliver his presidential address to the section of epidemiology and state medicine He will speak on the trend of fever hospital practice

---

Among the victims of German reprisal in Czecho-Slovakia is, we are informed, the chief of mental hospitals in Prague, Dr F Kafka, who was also director of the psychiatric clinic in the German University there

THURNAM —On Oct. 8 at Hayle Cornwall, William Rowland Thurnam, M D Durh, founder of Nordrach upon Mendip

Notes, Comments and Abstracts

BLOOD TRANSFUSION IN THE FINNISH WAR

Dr Erik Unonius and Dr Inga Schroder (*Nord Med* 1941, 10, 1046) tell us something of the problems encountered by the Finnish blood-transfusion service in the Russo-Finnish (as distinct from the Finno-Russian) war Many of the donors moved away from their homes during the early months of war and it became necessary to enrol new ones in large numbers in order to have a supply available for emergencies Donors are only accepted if the results of general examination, Wassermann and Kahn tests, and the sedimentation-rate are favourable Blood is taken directly into the transfusion apparatus Vichy-water bottles fitted with a special stopper were found to be satisfactory for the purpose The donor's hæmoglobin was estimated before the blood was taken, and it was found that the figure did not return to normal within 7 weeks of blood-taking The rate of restoration varied greatly between donors Men between 26 and 35 and women between 35 and 45 made up the loss most quickly, though elderly donors tolerated the loss of blood well Only group O blood was sent to the front, since grouping was impossible there Blood of other groups was used at the base hospitals as far as possible In field hospitals and casualty stations a mixture of equal parts of blood and normal saline was found to be the most useful for transfusion Stored blood showed similar changes whether treated with citrate or heparin The red cells were very resistant, but the whites disintegrated rapidly After 5 weeks the red cells were only down by 14%, but after a fortnight there were no undamaged white cells left According to Unonius and Schroder the destruction of white cells releases albuminous products in the blood which may account for the rigors occasionally seen The sedimentation-rate decreased rapidly, and after 2 weeks was 0 mm in one hour (Westergren) Blood-sugar fell quickly to a third and then remained constant The hæmoglobin percentage fell a little in the first week and then became steady Blood stored for 3 months was used for transfusion in two cases with no ill effects

HE'S A GOOD BOY

THE Cockney mother who went to the police-court to plead for her son put the idea of the Hawkspur camp in a nutshell "He's a good boy, yer honour, bar what he does" But in "The Hawkspur Experiment" (Geo Allen and Unwin Pp 192 6*s*) Mr David Wills describes in greater detail the attempt made at this voluntary camp of 70 youths to find a solution for delinquency not in discipline from without, but in control from within The workers at Hawkspur went all out to show the boy that though they *could not always approve* of what he did they always very much approved of him The Q Camps Committee, which continues to work among evacuated children, started the camp in May, 1936 When in January, 1940, the war made it impossible for the camp to carry on it was still chronically short of funds and officially unrecognised But it had the germ of a great idea and Mr Wills tells an enthralling story of pioneer effort The various forms of government adopted by the campers is in itself an instructive study of constitutional history The work of diagnosing the members of the camp was carried out by a selection and treatment committee, mainly composed of medical psychologists—though Mr Wills is careful to explain that he himself writes as a Christian and not as a psychologist—and the Institute for the Scientific Treatment of Delinquency gave a physical and psychometric examination as well as a psychiatric interview to each boy Happiness is a human birthright and delinquents are among those who have not found it, Mr Wills feels we should meet them not with retribution or punishment, but with treatment inspired by love

CONTRACEPTIVE TECHNIQUE

WHATEVER his views on the ethics of contraception the doctor needs to be well informed about its practical aspects, for sooner or later he is sure to be called on to give advice on them Many recently qualified men and women have been dismayed by their own ignorance when a patient asks for instruction on an efficient method of preventing conception In the medical c the subject is avoided, so that the young doctor is loss for theoretical data, and the patient's p knowledge of the subject may be better than his What is the safest, most reliable, least distasteful cheapest method of contraception? To answer important questions Dickinson and Morris have produ a concise well-illustrated booklet[1] All methods, g or bad, are reviewed, such dangerous devices as Grafenburg ring and the wishbone pessary are menti to be condemned All gynæcologists recognise t dangers of infection and perforation from these methods, which are not in any case certain prevent of conception since fœtus and ring have been seen occu ing the same uterine cavity The authors favour the condom for its simplicity, and the diaphragm pess but insist that both should be fortified by the c comitant use of a reliable spermicidal jelly They do n advocate postcoital vaginal douching, since it is un able and must be used immediately if it is to conf even a minor degree of protection They point out th dangers of using too strong a solution, most gynæ logists will recall cases of serious lysol or perchloride bu from this cause There are short chapters on perman sterilisation in the male and female, and an append on the organisation of a contraceptive clinic The book let will be useful to the man in practice and the final yea student

VINEGAR AND CIRRHOSIS

A CORRESPONDENT tells us of his sister who died some years ago from cirrhosis of the liver which the hospital physician thought to be alcoholic In fact the lady was almost a teetotaller, but she did take a great deal of vinegar, both poured over other food and as a drink The correspondent suggests that the vinegar may have been the cause of the cirrhosis The composition of vinegar varies, but apparently it may contain in addition to the main constituent, acetic acid, small quantities of formic and tartaric acids, free mineral acids combined sulphate, phosphates, caramel, sulphur dioxide and iron The acetic acid is converted into acetates and these ar quickly oxidised to carbonates and bicarbonates whic do no more than alkalinise the urine Some vinegar are fortified with sulphuric acid, but this should not b harmful in the doses likely to be taken. It does seem possible however that in large amounts vinegar ma produce a chronic gastritis, and on one view of the æti logy of cirrhosis this would open the way for bacteria t reach the portal circulation and might lead to cirrho The habit of drinking vinegar is much more common i women than in men, and some women take it a slimming remedy They may perhaps drink enough it to produce a mild gastritis which robs them of the appetite But the chapter is now closed, for slimmi is out of fashion and vinegar is getting as scarce a whisky

WEEK END COURSE IN WAR MEDICINE —A course in w medicine will be held at Shrewsbury Military Hospital Oct 25 and 26 Besides medical and surgical round t course will include lectures and demonstrations on eye injur gastroscopy, *plastic ear nose and throat* surgery, oxy therapy for resuscitation and anæsthesia in the field

MEDICAL CASUALTIES —In recent casualty lists Colo Cyril Popham, L R C P E , R A M C , and W S /Captain E Robertson, M B Glasg , R A M C , were posted as wound Lieutenant J Campbell, M B , R A M C , is reported to b prisoner of war

A PLEA FOR GRADUATION AT AN EARLIER AGE

A SPENCER PATERSON,
MA OXFD, MD EDIN F.R C P E, M.R C P, D PSYCH.

THE purpose of this paper is to discuss certain psychological and sociological aspects of the present system of medical education In what follows I am not referring to any particular medical school for I have had intimate experience of various universities not only in England but on the continent of Europe and America as well

Before this war the authorities were anxious that a medical student before graduation should not only be proficient as a doctor but should also have a good general education and knowledge of the world They therefore decided that the student should start his training late (18–19), have a longer medical course (6–7 years) and later take house jobs (1–2 years) Further, with the growing tendency to specialisation, a trip abroad would take another year, and so finally after perhaps another year or two, he might be able to settle down at the age of about 30 Now while everyone will allow that the highest possible degree of professional efficiency and general culture is desirable in the profession it will I think be apparent that this programme is not the best way of attaining it In the first place it takes not 6 or 7 years to make a good doctor but 30 or 40 years and the real points at issue are at what age we are to allow the boy to become a man, and at what age he is to be given a degree and encouraged to settle down and have a home of his own

The main contention of this article is that the average medical student should begin his university studies at the age of 16, and also to cite several well-recognised psychological and sociological principles in its favour This is nothing new, but a return to a much sounder system which has now been given up for some years It is generally agreed that education in Scotland has always been of a high standard and it is worth while comparing the life of a medical student 12 years ago at Edinburgh with that which appears to hold elsewhere today.

WHEN STUDENTS GRADUATED AT 21

Many youths started their course at 16 Matriculation at such an age ensured that it was the cleverer boys who took up medicine a fact which augured well for the future standing of the profession Again the tremendous number of scholarships coupled with the fact that the youth could graduate at 21 meant that ability rather than the state of the parents finances determined the selection of future doctors The boys had already had a good grounding in biology and often were proficient in at least one foreign language If a real love for learning is to be instilled, this will have occurred long before the age of 16

It is a psychological fact that the intellect of a boy of 16 has already been mature for 2 years and there is nothing that a boy of 18 can learn that is beyond the scope of one of 16 It does not appear that the years from 16 to 18 are very usefully employed for either the student learns the subjects for the first M B which he later re-learns at the university, or else he studies the classics This last subject seems of very little help in any way While it is essential if one is to master the English language that one should learn another as well, that second language ought to be a modern one Demosthenes wrote tolerably good Greek, and Cicero Latin although neither had been made to study Sanskrit I have discussed the value of the classics with others who like myself, have taken Honours Greats at Oxford, and the common view is that however valuable the complete university course a smattering of Latin and Greek is scarcely worth the trouble It does in fact contravene the law of "transfer of training," which states that the learning of one unrelated subject does not make it easier to learn another

On the other hand the student of 16 is much more enthusiastic and pliable If the authorities are afraid that the raw country lad will make an uncouth doctor, the obvious reply is "Send him to college when he is 16 and not 18 and then he will be more susceptible to the cultural influences of the university" These younger students did in fact take advantage of contacts outside medicine They mixed with students of other nations and with those in other faculties Apart from the university union, a student could discuss political and literary topics in the hall of the Speculative Society where Walter Scott and later R L Stevenson had once sat as secretaries, or argue medical problems in the Royal Medical Society, which Darwin and Lister had frequented in earlier days There were especially friendly relations between teachers and students, including a convivial banquet held once a year in the Royal College of Surgeons or Physicians Such cultivation of sentiment and appeal to tradition, counteracted any tendency of the university to become a mere cramming institution

I have often heard it said that no-one would recognise the raw country lad of 16 in the cultured graduate of 21, now hardly distinguishable from his fellow students who had been at Fettes or such other public school In order further to ensure that Scottish medicine should be imbued with culture in the widest sense there were a few scholarships to enable graduates in classics and philosophy or pure science to take up medicine and this practice might well be introduced in England The atmosphere of the university was remarkably free from the parade of pseudo-opulence which surrounds some medical centres My chief a renowned neurologist did not possess a motor-car, while the senior surgeon arrived daily at the university on a push-bicycle

While there is no psychological difference between 16 and 18 except the greater pliability and enthusiasm at the former age, there is a vast difference between 21 and 23 as the best age for graduation The youth who has begun at 16 is more easily absorbed in the activities of the university, and he tends to postpone his interest in affairs of the heart to a later date Under the present-day system however, the student appears to experience a definite sense of frustration after 21 The medical course seems to be endless This leads to emotional conflicts, and to friendships in many cases with women who in personality and status are inferior to those whom he would choose if he were frankly contemplating matrimony These clandestine associations which defy convention and morality, tend to dispel that idealism which is so necessary in the young doctor and substitute an unpleasant brand of cynicism In other cases the sense of frustration leads to a taste for tavern life or may reactivate some latent abnormal sexual trend It is tiresome for psychiatrists to have to treat resultant breakdowns which a more rational system of teaching would obviate

NURSES

An analogous state of affairs exists in the nursing profession The girl of 15 or 16 has already been intellectually mature for one or two years, and there is nothing which a girl of 19 can learn of which her sister of 15 is incapable Many suitable girls of 15 desire to become nurses, but because (in some schools) they have to wait till 19 they go into other occupations and stay there Yet the girl of 15 is so pliable and enthusiastic that the atmosphere of a great nursing college could completely captivate her until she was 20 She will by that time have mastered a profession which will stand her in good stead as an insurance policy against any possible accident to her husband in later years If a girl starts nursing at 19 she feels as if she is taking the veil She will finish her training at 24 or 25 and all this time she has the unhappy feeling that the best years of her life are slipping away. This of course only applies to the average nurse There will always be some excellent women who feel that nursing is their vocation and who have determined to remain as such throughout their whole life

The objection that the public will not have confidence in a young doctor or nurse rests on the most superficial psychological grounds Indeed, the nurse's uniform appears to be designed to make her look 10 years older than her age, a fact which favours the girl of 16 but greatly depresses the girl of 26 A youthful manner results from mental rather than physical factors, and the graduate at 21 who has been treated as a man and not as a boy will feel and look mature

EARLY MARRIAGE AND THE STATE

Up till now the authorities appear to have considered this problem purely from the individual's point of view Yet it is impossible to overestimate its importance from the point of view of the state With the tendency to postpone marriage into the thirties, the medical man is compelled to have a small family The reader will no doubt recall that most doctors of his acquaintance, and particularly specialists, are either bachelors or else have only one or two children If the family of two children comes to be considered normal, the day of England as a world-power is past Any country whose families average four children, given anything like equal conditions, is likely to oust one like ours, whose birth-rate replaces the present population by only 75% There is less incentive to fight to preserve freedom if this is to benefit not our own children but those of immigrants from a neighbouring neutral island or from Eastern Europe Since earlier marriage in the community always means a higher birth-rate, a heavy responsibility rests with any legislating body which encourages late marriage such as at present obtains in the medical and nursing professions

TRAUMATIC ANEURYSM OF POSTERIOR TIBIAL ARTERY, WITH FOOT-DROP

IAN MACPHERSON, M D LEEDS, M R C P, MAJOR, R A M C, MEDICAL TUTOR, UNIV LEEDS

H S SHUCKSMITH, B SC M B LEEDS, F R C S, MAJOR, R A M C, SENIOR SURGICAL TUTOR

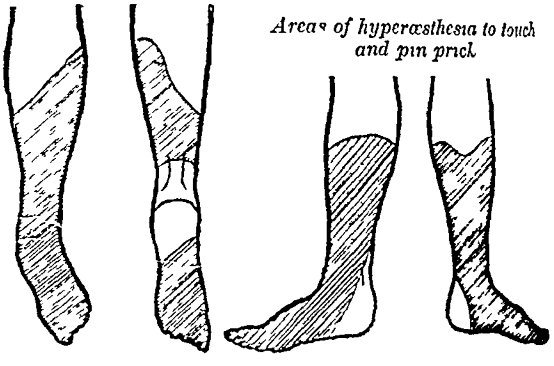
THE case which we are describing followed a bullet wound of the leg and showed not only the features of a traumatic aneurysm but also foot-drop Owing to the proximity of the wound to the external popliteal nerve, trauma to the nerve was at first considered to be the cause of the paralysis Had it been recognised that ischæmia might have damaged the external popliteal nerve the aneurysm might have been found much earlier

The development of an efficient, or more than efficient, circulation in a limb several months after an injury producing an aneurysm has been recorded by Lewis (1940) and Holman (1940) It is well exemplified by the course of this patient immediately after operation when it seemed that in addition to the obvious aneurysm of the posterior tibial artery the anterior tibial artery might also be affected A well-defined area of hyperæsthesia in the leg, distal to the aneurysm, was present before operation and persisted, its genesis is difficult to explain

CASE-RECORD

A man, aged 20, was wounded near Dunkirk on May 27, 1940 The upper part of his right leg was penetrated obliquely by a rifle bullet entering the outer side near the neck of the fibula and emerging in the middle of the calf behind There was considerable arterial bleeding from both wounds and the soldier showed great ingenuity in constructing a tourniquet from his lanyard and jack knife when he found that the first field dressing failed to stop the bleeding Three days elapsed before he reached the base hospital in Britain, and during this time he had considerable pain in the leg and complained of coldness in the foot His wounds were healing satisfactorily and radiography showed a comminuted fracture of the head of the tibia, the leg was immobilised in plaster Attempts to walk in the plaster produced so much pain and cramp in the region of the exit wound that the plaster had to be removed Further attempts at immobilisation in plaster had to be abandoned because of the same symptoms It was now discovered that he could not dorsiflex his foot although some power of dorsiflexion of the great toe remained The dorsum of the foot and the region just above the ankle felt numb Splinting the leg and massage resulted in considerable improvement of the foot drop, but general aching in the leg and foot persisted, and there was occasional slight swelling of the foot He was discharged to duty in September The pain in the leg on walking and standing led to his readmission to hospital At this time, 3½ months after the injury, he noticed an area tender to touch about the size of the palm of the hand just above the outer side of the ankle This region felt bruised and when it was tapped pain like an electric shock shot down to his big toe In addition, the observant patient had noticed for 6 weeks an increasing pulsation at the back of the right knee

On admission under our care in February, 1941, with [illegible] infection of the upper respiratory tract, he mentioned [illegible] aching pain in the right calf and foot on walking and [illegible] occasional sharp pain shooting from the ankle to the big toe while sitting still The right calf was 1½–2 in larger in girth than the opposite leg The healed entrance wound was situated in front and slightly medial to the neck of the fibula and the exit wound was in the middle of the calf about 5 in below the bend of the knee The track had extended downwards, inwards and backwards, passing immediately below the tibiofibular joint through the interosseous membrane Pulsation of the calf was visible just above the exit wound and the veins were more prominent in that leg There was a somewhat localised expansile pulsating swelling 1–1½ in long, extending upwards from the exit wound A thrill clearly felt over the swelling extended to the upper limit of the popliteal space and could be felt in the posterior tibial artery at the ankle Pulsation in the femoral artery at the groin was more easily felt on the right side A loud high pitched murmur, systolic in time, was heard 2 in higher and a little lower than the limits of the thrill It was particularly loud in the popliteal fossa and over the external malleolus, possibly owing to bone conduction in the latter situation. The systolic blood pressure taken at mid thigh was 225 mm. Hg, but the diastolic pressure could not be recorded by auscultation, the pressure in the left thigh was 185/105 mm A sharply demarcated and constant area of hyperæsthesia to touch and pinprick is shown in the figure by shading There was no difference of temperature between the two feet on ordinary examination but the right foot became redder than the left when dependent The right foot could be dorsiflexed almost to a right angle but the power was still diminished There was no cardiac murmur nor enlargement of the heart and the general condition of the patient was good The radiogram showed no evidence of fracture but erosion of bone on the opposing surfaces of the tibia and fibula just below the superior tibiofibular joint



Areas of hyperæsthesia to touch and pin prick

Operation —The limb was exsanguinated and a tourniquet applied across the upper third of the thigh A midline incision from the upper part of the popliteal fossa to the outer margin of the tendo achilles was used The structures of the popliteal fossa were dissected clear and there was no evidence of damage to the nerves The vessels in the posterior compartment of the leg were exposed by dividing gastrocnemius in the line of its fibres and the tendon of plantaris, and by incising soleus A sac, densely adherent to surrounding muscles and to the posterior tibial and the branches of the internal popliteal nerve, was separated This sac, the size of a walnut, interrupted the course of the posterior tibial artery for about 2 in and the posterior tibial vein was obliterated in its wall, the upper extremity was about ½ in distal to the bifurcation of the popliteal artery The anterior and posterior tibial arteries were of equal size In attempting to free the deeper portion of the sac it was soon apparent that a larger part of the aneurysm lay deep to the plane of the interosseous membrane and coincided in site with the erosion of bone seen by X rays The upper border of this deep part lay snugly under the lower fibres of popliteus The posterior tibial vessels were ligated above and below the sac and the hour glass like aneurysm removed Severe hæmorrhage resulted on release of the tourniquet and it was feared that the anterior tibial artery was also affected Bleeding was controlled by pads of gauze stepped up in size and liberally soaked in turpentine The skin was lightly sutured There s an adequate circulation in the limb immediately after ration The wound suppurated but the infection quickly bsided after the removal of the pack and Vaseline gauze inage The wound was closed 21 days after operation

The specimen consisted of two dilated portions connected a narrow neck. The posterior sac was relatively smooth d thick walled but the larger anterior part was friable and in and had relied for its support on direct apposition with ne Histologically the smaller of the sacs was arterial in igin and the larger was purely connective tissue, the whole nforming to the picture of a traumatic arterial aneurysm.

DISCUSSION

The history of arterial bleeding at the time of injury ollowed by coldness of the foot and severe pain, like intermittent claudication, in the calf on walking indicated rterial damage We did not make observations to ifferentiate between traumatic arterial and intravenous neurysm as outlined by Holman (1928) and Porter 1938) The two may be distinguished by measurement f the venous pressure in the limbs, the rate of bloodow and oxygen content in the veins, and observations n the pulse-rate following pressure over the aneurysm ufficient to obliterate the thrill (Branham's phenomenon) The absence of cardiac murmurs and decompensation and the systolic timing of the thrill indicated a traumatic arterial rather than an arteriovenous neurysm (Makins 1919 and Hoover 1924) The blood-pressure readings in the femoral arteries differ widely (right 225/? and left 185/105 mm Hg) It is difficult to see how the systolic pressures can differ on the two sides, the diastolic pressure on the right by auscultaory methods gave a reading of nil The blood-pressure distal to the region was not recorded

Treatment had been directed for many months to the partial external popliteal palsy without the aneurysm being suspected. Although the track of the missile was near branches of the external popliteal nerve it had not directly damaged the nerve nor was the aneurysmal sac in contact with the nerves It is however, well known that nerves may be actually traumatised by the ateral explosive force of a missile Is it possible to xplain the popliteal palsy on the basis of ischæmic damage to the nerve? It is probable that there was schæmia of the leg during the development of the arterial hæmatoma and Lewis (1936) has shown that nerves recover after 12–20 hours ischæmia, the recovery being slow and dependent on regeneration The area of hyperæsthesia of the leg does not correspond to the distribution of somatic nerves and clinically the condition resembled minor causalgia This state is common after injury to blood-vessels (Homan 1940) and is considered to be a reflex phenomenon from the injured segment of artery The hyperæsthesia in this case has persisted after removal of the aneurysm

Holman recommends operation without a tourniquet It is true that one might thus appreciate better the size of the vessels involved but it seems easier to be able o open the aneurysmal sac at once and quickly explore ts limits The method of arresting bleeding in an naccessible part of a limb by using small pieces of gauze graduated in size (Billroth pack) and soaking these in turpentine, as recommended by Grey Turner, probably saved he patient s limb Holman (1940), in reporting 8 successful cases of operation for aneurysm in the limb, noted that provided the aneurysm has been present for some months here is no danger of gangrene after its removal

SUMMARY

A case of traumatic aneurysm of the posterior tibial artery with associated foot-drop is described

We consider that the nerve paralysis resulted either from ischæmia or from the lateral explosive force of the missile The nerves were normal in appearance and well away from the aneurysmal sac

Hyperæsthesia of the leg persisted after removal of he aneurysm

The lapse of 9 months after injury made it certain that there would be an adequate blood-supply after operation

The Billroth pack and turpentine were found to be of value in arresting hæmorrhage

We are indebted to Colonel F Whalley for permission to publish this case

EFFECT OF CALCIUM IN A CASE OF AUTOHÆMAGGLUTINATION

H J PARISH, M D EDIN, M R C P E
R G MACFARLANE, M D LOND
(Wellcome Physiological Research Laboratories, Beckenham)

AUTOHÆMAGGLUTINATION is usually regarded as synonymous with non-specific cold agglutination or panagglutination of Mino—i e, the clumping which is sometimes observed when red cells are mixed at 0–5° C. with serum from the same person The use of the word is discussed fully by Wiener (1939) In rare cases this clumping also occurs at room temperature and Boxwell and Bigger (1931) were in favour of restricting the term to agglutination at this higher temperature Their paper included a review of 22 authentic cases of the condition which had been reported before 1931 They were careful to exclude pseudoagglutination or excessive rouleaux formation and the Thomsen phenomenon, which is agglutination caused by bacterial action McCombs and McElroy (1937) obtained records of 38 authentic cases, 5 of the subjects were in normal health, while in many others the condition was associated with either anæmia or some interference with the function of the liver as shown by jaundice and enlargement of the liver Greenwald (1938) described autohæmagglutination in a case of acute hæmolytic anæmia and noted the occurrence of autohæmagglutination in pernicious and other severe anæmias, acholuric jaundice paroxysmal hæmoglobinuria, severe pneumonias and staphylococcal septicæmia Gray Greenfield and Lederer (1940) reported a fatal case of benzene poisoning associated with definite autohæmagglutination which occurred " only at a temperature below that of the body The effect of the autoagglutinin was eliminated by heating the patient's serum and cells to body temperature." Dockeray and Sachs (1941) observed autohæmagglutination in a case of acute megalocytic anæmia

We have recently had a case of autohæmagglutination which differed in some respects from the one described in detail by Boxwell and Bigger and also presented certain features which have not hitherto been reported

CASE-RECORD

A male laboratory assistant, aged 27 Mother died of heart failure Father, two brothers and one sister alive and well One brother had attacks of urticaria during childhood and now suffers from severe hay-fever every summer Neither father (group A) nor one brother (group O) showed autohæmagglutination Patient had been in good health for years, but in childhood had frequent attacks of urticaria, angioneurotic œdema gastro intestinal disturbance and headache Recently had only once suffered from mild urticaria, weals being confined to left leg Last attack of severe abdominal symptoms and headache was in 1938, on account of associated dyspnœa pneumonia was suspected, but none was detected, so symptoms thought to be allergic in origin Responsible allergen not discovered Angioneurotic œdema with swelling of lips, used to occur almost weekly, but only two minor attacks during past year No history of jaundice, hæmaturia or hæmoglobinuria, chilblains, anæmia, asthma or hay-fever

Attention was first directed to condition by chance observation that patient s serum, which belonged to group O, agglutinated not only groups A and B cells, against which group O serum is usually tested, but also group O cells which are seldom used for test purposes with group O serum Altogether, patient's serum was tested against cells of 15 group O subjects and produced agglutination in every instance at room temperature, also agglutinated cells of groups AB, A and B and of patient himself In most instances cells were obtained by taking few drops of blood into 1% sodium citrate solution, and were *unwashed* Less definite clumping occurred when blood was added to patient's serum direct, without use of

CASE 2—A soldier, aged 22, was admitted to an E M S hospital on June 6 complaining of malaise and shivering, painful throat and a lump in the left side of his neck of about 36 hours' duration Temperature 102 6° F, pulse rate 110, flushed but not looking or feeling very ill Enlarged tender glands in both sides of neck, supraclavicular fossæ and left groin Spleen and liver not felt No rash Tonsils large and fleshy, but not obviously infected, no ulceration or exudate on fauces but a throat swab on June 9 showed a heavy growth of hæmolytic streptococci Hæmatological and serological changes are shown in table II By June 13 the spleen was definitely palpable, epitrochlear glands on both sides were enlarged, and more enlarged glands had appeared in the axillæ and neck The temperature, having swung aily between 99° and 102° or 103° F, fell abruptly to normal n May 15, when bile appeared in the urine and slight jaundice as noted in the skin and conjunctivæ Serum from blood aken on the previous day for the Paul Bunnell test was ound to give a quantitative van den Bergh reaction of 3 5 nits (normal range up to 1 unit)

On June 16 skin jaundice was barely visible but the urine till contained a trace of bile On June 17 the skin was clear nd no excess of urobilin could be shown in the urine The otal duration of jaundice was thus about 48 hours By une 21 the patient was feeling well, and he was discharged a week later

TABLE II—FINDINGS IN CASE 2

June	9	13 & 14	19 & 21	27 & 28

The sheep cell agglutination test used for both cases was that of Stuart and others (1934), who modified the riginal Paul-Bunnell technique In both cases the heterophile antibody was absorbed by ox-cells and not y guineapig kidney, thus fulfilling the criteria for landular fever antibody as finally laid down by Davidsohn (1937) The strongly positive Paul-Bunnell eaction in case 1 after sulphonamide therapy is interesting in view of the suggestion (*Lancet*, 1941, i, 84) that the ulphonamide drugs might suppress antibody formation, lthough Logan (1941) mentioned a case in which heavy ulphapyridine therapy did not have this effect In case the Paul-Bunnell titre was low despite the fact that no ulphonamide drugs had been given at all

Frequent red cells of the "target" type were seen in blood films from both cases during their periods of jaundice, these cells were described in obstructive jaundice by Barrett (1938)

DISCUSSION

I have found 13 cases of glandular fever with jaundice in the literature (Downey and McKinlay 1923, Mackey and Wakefield 1925, Stuart et al 1934, McKinlay 1935, de Vries 1938, Svaar-Seljesaeter 1939, Fowler and Tidrick 1940) Cathala and others (1939) recorded an alleged case, but the clinical and pathological data were not entirely convincing Tidy (1934), in the Lumleian lectures, said that jaundice was a rare complication of glandular fever, especially in childhood, and that it commonly developed after the glandular enlargement, although it might occur before in the febrile type de Vries (1938) recognised 3 types of jaundice in glandular fever (1) a "forme icterique a debut ganglionnaire" where glandular enlargement was prominent, and jaundice developed during the course of the disease, (2) a "forme a debut icterique" where jaundice was the first symptom and the other features of glandular fever followed, and (3) very rare cases in which jaundice and slight pyrexia were the only symptoms, and the diagnosis of glandular fever rested on hæmatological findings and a positive Paul-Bunnell reaction The first case recorded here appears to be an example of the febrile type of disease "a debut icterique," and the second of "forme icterique a debut ganglionnaire"

In the recorded cases the jaundice seldom lasted longer than a week, and was usually considered to be of obstructive origin rather than due to liver-damage or infection of the biliary passages Few laboratory details were given, but frequent mention of pale stools and dark urine containing bile-pigments, with normal liver-function tests in several cases, supported the general opinion The cause of biliary obstruction was assumed to be pressure from enlarged glands in the liver hilum, by analogy with the mesenteric glands which can be enlarged or palpable and cause abdominal pain The liver is enlarged as a rule whether jaundice is present or not

The main interest of jaundice in glandular fever lies in the diagnostic difficulties raised when it occurs before glandular enlargement is prominent and glandular fever suspected Catarrhal jaundice and cholecystitis are mentioned as diagnostic pitfalls, as well as the pre-eruptive stage of syphilis, because the Wassermann reaction is often positive in glandular fever and thus may be associated with enlarged glands and a subsequent rash de Vries (1938) even advocated examination of a blood film and a Paul-Bunnell test in every case of jaundice, and these investigations are certainly desirable in cases, such as case 1, which present unusual clinical features In this case suspicion was aroused because the patient was not very ill despite a high temperature, and the lack of pain and tenderness excluded an acute gall-bladder lesion, while the absence of nausea, the high temperature and raised pulse-rate were against catarrhal jaundice—yet the deeply bile-stained urine indicated an obstructive jaundice This last feature, coupled with the few palpable glands, the enlarging spleen and recent history of sore throat, suggested the true diagnosis

SUMMARY

In 2 cases jaundice was associated with glandular fever In one case jaundice was prominent and preceded the usual glandular enlargement, while in the other it occurred as a transient feature during the course of an otherwise typical attack of glandular fever Hæmatological findings and positive Paul-Bunnell reactions confirmed the diagnosis in both cases

The jaundice is of obstructive type and probably arises from enlargement of glands in the liver hilum

Examination of a blood film and a Paul-Bunnell test are desirable in cases of obstructive jaundice of obscure causation

My thanks are due to Dr A M Barrett of the pathological department of Cambridge University for his help with the blood examinations and Paul Bunnell tests, and to Dr N R Lawrie, biochemist at Addenbrooke's Hospital, Cambridge, for the biochemical tests

References at foot of next page

normal Through thin, lax abdominal wall edge of spleen can be felt at costal margin At ends of digits there is an extremely soft putty like pulp, over which are bluish spots, and small dry sloughing patches with definite lines of demarcation Immersion in water to 10° C makes fingers turn first blue and then white and starts tingling On warming they turn bright red Peripheral pulsations everywhere good Blood pressure in right brachial artery 112/80 mm Hg, same elsewhere

Urine normal, no blood or staining Blood-films had to be made on warmed slides, or the cells clumped before spreading Examination by Dr A M Barrett showed neutrophils 38 5%, eosinophils 8%, basophils 1%, small lymphocytes 39%, large lymphocytes 13 5% Platelets appear in usual numbers Red cells show slight anisocytosis and slight poikilocytosis Few small mis shapen red cells present Mean diameter of red cells 7 4 μ for 50 cells Hæmoglobin 52% Red and white cell counts not made because of difficulty in preventing clumping, even after dilution with saline or using anticoagulants Fragility tests performed by Dr Barrett's method and carried out at body temperature showed no abnormality Bleeding time, 1¼ min Clotting time 3¼ min (Wright's method) Wassermann reaction negative

Hæmagglutination tests were performed by Dr Taylor and his staff at the Galton laboratory The titre of the agglutinins was 1/4000 for the homologous red cells Heating the serum to 55° C for 25 min did not destroy the agglutinins

HÆMAGGLUTINATION TESTS

Cells	Readings at 4° C and at room temperature				Readings at 37° C			
	Serum			Saline	Serum			Saline
	a	b	Case 2		a	b	Case 2	
O	—	—	C	—	—	—	—	—
A	—	C	C	—	—	C	C	—
B	C	—	C	—	C	—	C	—
Case 2	C	C	C	C	—	—	—	—

C indicates clumping, — indicates no clumping

From the table it can be seen that the patient's blood is group O An agglutinin is present in her serum which clumps cells of all groups in the cold Her cells likewise clump with all sera (including her own) in the cold It would be necessary in grouping this patient's blood for transfusion to perform the tests at 37° C Otherwise the cold agglutinin effective at room temperature would produce an apparent clumping in the cross agglutination test The red cells clump themselves in saline in the colder room (It was also found that six prolonged washings of the cells failed to prevent this) It was further noted that the agglutination which occurs in the cold was reversible when warmed

Apart from the similar vascular changes and the presence of a powerful cold agglutinin in both cases there are other points of similarity in these two cases and some differences Both are married women over 50 following domestic occupations They were in good health until about two years before seeking advice, which they did during or soon after the very cold winter of 1939–40 on account of numbness and tingling of the hands Both showed a moderate secondary anæmia and a definite eosinophilia On the other hand they were physically quite dissimilar one plump and fresh looking and the other wasted and icteric (the former seen some 12 months later however was definitely jaundiced and gave a positive indirect van den Bergh of 1 5 mg per 100 c cm) Their differential white counts were widely different and their blood-groups were different

DISCUSSION

Raynaud's syndrome is characterised by paroxysmal, intermittent colour changes of the extremities, precipitated by cold, and without clinical evidence of blockage of the large peripheral vessels The theory of ætiology commonly brought forward is that of Lewis who postulates an inherent abnormality of the digital arteries rendering them unusually sensitive to cold The fault, according to his demonstrations, seemed to be within the vessel wall rather than in the nerve-supply thereto In the two cases described here the blood also shows the phenomenon of cold-autohæmagglutination We think that so unusual a combination suggests a possible causal relationship Witts (1936) has pointed out that in paroxysmal hæmoglobinuria e frigore, the syphilitic disease in which the well-known Donath-Landsteiner cold-sensitised hæmolysin is present, Raynaud's syndrome sometimes occurs with considerable severity Autohæmagglutination is also known to be associated with anæmias and dysfunction of the liver (Boxwell and Bigger 1931) but latter are not hypersensitive states, it may also appear in otherwise normal persons It is, however, generally recognised that people with one form of hypersensitivity often show others as well, and it seems probable that in our cases cold hypersensitivity played a part in the production of both the agglutination and the Raynaud's syndrome, in the latter the arteriolar musculature would be the sensitive tissue

McCombs and McElroy (1937) have reported a case and have suggested the term reversible autohæmagglutination They have collected further cases from the literature making a total of 38 They quote the Japanese authors Iwai and Mei-Sai who had already demonstrated intracapillary clumping in vitro, and had suggested that this might play a part in the production of Raynaud's syndrome McCombs and McElroy believe that plugging with agglutinated cells would explain all the vascular symptoms in their case, which showed some degree of peripheral arteriosclerosis In our own two cases the spastic element was evidently playing a large part

SUMMARY

In two middle-aged women Raynaud's phenomena were associated with powerful cold agglutinins in their sera

It is suggested that there was a causal relationship between the two conditions Probably cold hypersensitivity played a part in the production of both

We are indebted to Mr Ivor Lewis, medical superintendent of North Middlesex County Hospital, for permission to publish case 1, and to Professor Ryle for permission to publish case 2

GLANDULAR FEVER WITH JAUNDICE

REPORT ON TWO CASES

LAURENCE MARTIN, M D CAMB, M R C P
RESEARCH ASSISTANT DEPARTMENT OF MEDICINE, CAMBRIDGE UNIVERSITY, PHYSICIAN, E M S

THERE are few recorded cases of jaundice as a complication of glandular fever and little mention of it in most modern textbooks, though brief allusions are made by *Tidy (1937) and Whitby and Britton* (1937) In the first of the following two cases jaundice and fever were presenting symptoms before there was notable glandular enlargement, while in the second case transient jaundice appeared in the course of an otherwise characteristic attack

CASE 1—A soldier, aged 21, was admitted to an E M S hospital on May 7, 1941, having been in a field ambulance since April 30 with headache, sore throat and pyrexia up to 103° F No improvement had followed sulphapyridine (? 1 g) 4 hourly for 48 hours and subsequent sulphanilamide (? 1 g) 4 hourly for 4 days Slight jaundice was noted on May 5 which was deeper on May 6 when splenic enlargement was found

On May 7 he had slight jaundice of the skin and conjunctivæ, no rash was present or had been noted previously Temperature 99 4° F, pulse rate 90 Mouth and tongue dry and glazed, sordes on lips, but no ulceration or exudate on tonsils or fauces No abdominal pain or tenderness, liver not enlarged, Traube's space dull to percussion but spleen not definitely felt A few lymph glands palpable, but not tender or strikingly enlarged, in the left supraclavicular fossa, axillæ and groins Urine contained much bile, but no albumin or blood Van den Bergh reaction delayed direct Throat swab on May 7 a few colonies of hæmolytic streptococci *Hæmatological* and serological findings are shown table I

WELL-LEG TRACTION APPARATUS FOR REDUCING FRACTURED FEMORAL NECK

E MERVYN EVANS, M B CAMB, F R C S
CTING SURGICAL AND ORTHOPÆDIC REGISTRAR AT THE MIDDLESEX HOSPITAL, SURGEON, E.M S

THE principle of well-leg traction may be applied with advantage to the reduction of fractures of the neck of the femur prior to their fixation by the insertion of a Smith-Petersen pin, by this method a rapid and atraumatic reduction is obtained in the patient's bed, whether in a hospital or at home, and X-ray confirmation is available before the operation is undertaken When the reduction is satisfactory the patient may be moved in the apparatus without fear of disturbing the fracture The method thus has several advantages over other methods commonly employed Reduction by manipulation immediately before operation is satisfactory in most cases, but occasionally accurate reduction is not btained even after several attempts, and, with the heatre and X-ray teams waiting to proceed, the surgeon may be tempted to accept an imperfect reduction Reduction by weight extension in bed is relatively cer-ain, but movement of the patient to the theatre is difficult and the fracture may be displaced during the process Reduction on a Hawley table overcomes these difficulties, but the method is restricted to those institutions where the necessary equipment is available With egard to the complete-bed technique many surgeons consider that the insertion of a Smith-Petersen pin is not a suitable operation to be performed in bed whatever the advantages of the method

With these points in mind I have made a modification of the Roger-Anderson apparatus to be used with strapping extension The speed with which the fracture is reduced allows of heavy extension (40–50 lb) being used without fear of skin lesions

The splint (fig 1) consists essentially of a long metal stirrup which is incorporated in a thickly padded plaster extending from the foot to the mid-thigh on the sound side The sides of the stirrup are prolonged below the foot and bent inwards so that they run together to a point 18 in below the foot on the injured side A pulley is fixed to the splint at this point, and over this screw traction is applied to the injured limb, a spring balance is interposed between the screw and the strapping extension to measure the amount of traction I have found it convenient to incorporate a cradle attached to the sound limb, from which the injured limb may be suspended Internal rotation of the injured limb is obtained by attaching a broad strip of adhesive strapping to the outer side of the limb and fixing it to the over hanging cradle

With this splint a fracture of the neck of the femur is reduced very quickly, and with the minimum of disturbance to the patient The splint is applied in bed without an anæsthetic, though a sedative will be found of advantage It is best to apply heavy traction (up to 40–50 lb) at first, reducing this to 20–30 lb as soon as the greater trochanter has come down to its normal level Anteroposterior and lateral radiograms are taken, and if reduction is satisfactory the patient is transported to the theatre at leisure If reduction is incomplete traction is continued until the desired result is obtained The operation is performed with the splint in position and the extension on, but as soon as the pin has been inserted the extension is removed so that the fracture may be impacted, after this the apparatus is removed

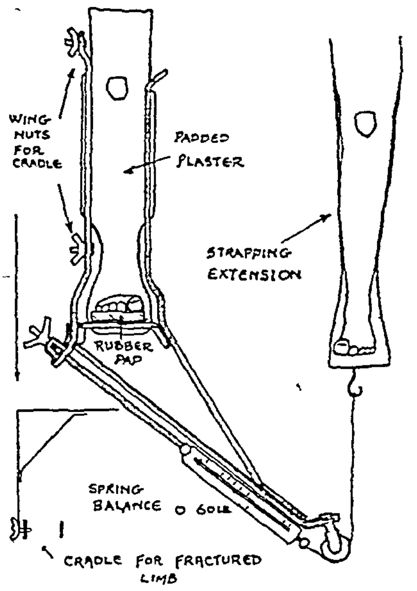

FIG 1—Diagram of well leg traction apparatus

I have treated three cases by this method and in all reduction was obtained within 12 hours The principle of heavy fixed traction is the same as that employed on a Hawley table, and reduction must be very rapid I am satisfied that if it had been convenient to X ray these cases earlier the same result would have been obtained

The fixation of the sound limb necessitates the use of a different technique from that usually employed for the lateral radiogram A cassette is thrust as high up into the perineum as possible so that it faces upwards towards the injured side, and the X-ray tube is directed downwards from the loin on the injured side at a distance of 36 in from the cassette The tilting of the pelvis downwards on the injured side, owing to the pull of the screw-traction, makes a good lateral view of the head and neck of the femur possible Fig 2 illustrates a case treated by this method.

SUMMARY

A method of reducing fractures of the neck of the femur by well-leg traction in a modified Roger-Anderson apparatus is described It ensures a rapid and atraumatic reduction, obtained in the patient's bed and confirmed by X ray before operation The fracture can be immobilised and the patient transferred to the theatre without fear of redisplacement, and the fixation is maintained until the insertion of a Smith-Petersen pin has been completed

I am indebted to Mr A S Blundell Bankart for his help and advice, and to Major Eric Samuel for the development of the X-ray technique The instrument has been made for me by Messrs Down Bros

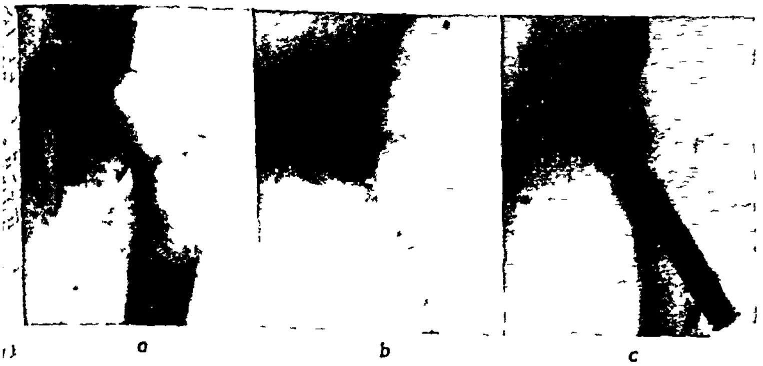

FIG 2—Fractured neck of femur (a) Before reduction (b) After reduction in well leg traction apparatus (c) After insertion of Smith-Petersen pin

---

"There are some things worth waiting for even in war, and high among these is the maturity which comes to boys of ability and character after even a brief experience of University life and work. I have found the most convinced and outspoken believers in the value of this academic process even for the purposes of war among the representatives of the Fighting Services I could wish that this fact were better known in the schools, where the natural but mistaken feeling still lingers that a University education, however compressed and accompanied by Service training, is in these days a privilege which the highspirited should perhaps forgo"—G S GORDON, vice chancellor of the University of Oxford in his valedictory oration to convocation on Oct 8

TETANY FOLLOWING PROLONGED LACTATION ON A DEFICIENT DIET

A B ANDERSON,
PH D CAMB, M R C S
CLINICAL BIOCHEMIST TO THE GLASGOW ROYAL INFIRMARY

ALEXANDER BROWN,
M B GLASG, F.R F P S G, M R C P E
EXTRA ASSISTANT DISPENSARY PHYSICIAN AND PATHOLOGIST

A WOMAN of 42 was first seen by one of us on April 23, 1941, as an outpatient She gave a history of recurrent attacks of painful muscle spasm, the first experienced during the night two months previously, and affecting the forearms and hands A week elapsed between this and the second attack in which trunk and limbs were involved The description of the posture produced by the attack left no doubt that the spasms were typical of tetany of unusual severity Major attacks occurred with increasing severity and frequency, and were accompanied by great pain In the later weeks of the illness they were of almost nightly occurrence, varying in duration from a few minutes to two hours At the end of an attack the disappearance of spasm preceded by as much as an hour the disappearance of all discomfort Minor symptoms occurred frequently by day as well as by night, and consisted of paræsthesiæ in the extremities and a feeling of stiffness in the muscles of the limbs Even in the major attacks the higher centres were unaffected Amenorrhœa had been present ever since the last pregnancy until three weeks before admission when uterine bleeding began

She gave a vague history of painful spasms of the hands and feet in childhood, rather similar to the attacks described above After a year's disability the condition subsided, and until the present illness she had been in excellent health She had had 7 children, of whom 1 died at the age of 9 months from bronchopneumonia, the others were alive and well All were normal spontaneous deliveries The first 6 were breast fed for 9 months, but the youngest child at the age of 21 months was still at the breast when the patient was seen by us Questioned about her diet, she said that for breakfast she always took porridge without milk, with an egg once a week Her midday meal consisted mainly of potatoes with occasionally mince or other form of meat A milk pudding was sometimes taken, but she was quite definite that in the week she did not have more than ½ pint milk, except for the small amount of condensed milk she had in her tea Other meals consisted chiefly of bread and tea

The patient was a poorly nourished sallow rachitic female of short stature Though mentally very listless, she presented to an extreme degree the many clinical signs of undue muscle irritability associated with tetany Chvostek's sign was readily elicited, and Trousseau's was uniformly positive within 1–2 minutes of compression of the upper arm Though the peripheral nerves and muscles were hyperexcitable to percussion, the tendon reflexes were all sluggish and the abdominal reflexes, during her stay in hospital, could not be elicited The results of general examination of the patient were in great part negative, though the vaginal bleeding still continued B P 100/60 Red cells 3,300,000, white cells 6400, Hb 9 6 g % The breasts still contained milk

While under observation, and before treatment was begun, she had occasional discomfort and paræsthesia in the extremities Slight localised, but no generalised, tonic spasm occurred spontaneously during these few days most prominent complaint was pain in the lower region

Radiological findings (Dr. R K Harper) —" There are n changes in the skull or pelvis There is thinning of the cortex of the femora and tibiæ with uniform decalcification of the extremities of the long bones Slight decalcification of the fibulæ and bones of the forearms is also seen There i slight bowing of the left tibia which may be due t these changes although the bowing may be old as there i probably insufficient decalcification to account for the recent bowing "

Clinical progress —The patient was admitted to Dr Dav Smith's wards on April 29, 1941, and subsequently transferr on May 3 to the metabolic wards for investigation Lactat was stopped on admission Treatment was begun eight day later and consisted solely of a mixed-diet of 2700 calorie including 1½ pints of milk daily The result was comple relief from muscle spasm and subjective sensory disturbance By May 15 there was no evidence of muscle irritability Th vaginal bleeding was much diminished and by the 20th had ceased entirely She was discharged on May 30, and a mo later was seen as an outpatient She was then still rather pal but her listlessness had gone, there was neither subjective n objective evidence of tetany She was sent to a convalescent home where she received extra milk A scale preparation of iron was prescribed for the anæmia

Biochemical investigation —April 30 and May 6, serum calcium 6 9 mg per 100 c cm May 7, treatment begun May 13, serum calcium 9 4 mg, plasma inorganic phosphoru 2 7 mg per 100 c cm May 25, serum calcium 10 2 mg May 30, discharged June 20, serum calcium 9 0 mg per 100 c cm

Calcium balance —Three day period beginning May 20 Calcium in urine was estimated by the method of Shohl and Pedley (1922), in food and fæces by that of McCrudden (1909–10, 1911–12).

Daily output—Urine	0 075 g	*Daily intake*		1 204 g
Fæces	0 694 g		*Balance*	+ 0 435 g
Total	0 769 g		*Per cent retention*	27

Too great stress cannot be placed on the calcium balance taken for one period of three days But it is obvious that a very considerable retention of calcium was taking place

COMMENT

This case of early " osteomalacia " with tetany present several interesting features The poor diet deficient in calcium combined with the drain of repeated pregnancies and prolonged lactation was sufficient to produce definite clinical, radiological and chemical evidence of gross calcium deficiency Our impression is that such a deficient diet is common in the poorer classes of Glasgow in spite of contrary statements that have been mad To elicit a true account of the average diet requir careful inquiry, only detailed questions as to the actual food eaten day by day will determine the true intake Our patient is a case in point, when first questioned th impression was gained that her diet was adequate and it unsatisfactory nature was discovered only after detailed questioning The rapid recovery from tetany and hypocalcæmia under treatment with a high calcium milk diet assisted by weaning is in striking contrast t the lack of response in tetany due to non-absorption of calcium such as that found in non-tropical sprue, and is comparable to the rapid absorption of calcium in hunger osteopathy reported by Crawford and Cuthbertson (1934)

As Mellanby (1933) says, " It is probable that many women suffer some osteoporotic change owing pregnancy " While this is an extreme case in which calcium deficiency was brought to light by the occur of tetany, there is no doubt that it is an example, only in degree, of general calcium deficiency in lac women living under similar conditions

We are much indebted to Dr David Smith for the tunity to investigate this case

THE LANCET

LONDON: SATURDAY, OCTOBER 25, 1941

LIGHTENING THE LOAD

In January national health insurance will be extended to half a million people with incomes up to £420, and whether or not doctors approve of the extension a number of them will find it brings an additional burden to what was already becoming a harassed life. The addition may not sound numerically large—in 1938 the 16,840,000 insured persons were shared on 16,200 doctors' lists—but there are now fewer doctors in panel practice and the newcomers will not be evenly distributed on the lists. Moreover they are drawn from the income group which have hitherto found the doctor's bill particularly hard to meet and have therefore stinted themselves of medical attendance even beyond the limits of safety. They will now come to the doctor for many ailments which they would previously have treated themselves or left untreated, and some of them, from ignorance of the rules and customs of insurance practice, may give the doctor more trouble than they need and not get as good attention as they might. The insured person, like his doctor, is bound by a code of rules; but, whereas the doctor who breaks his may well find his quarterly cheque reduced by way of fine, the patient's shortcomings are overlooked unless they affect his relations with the approved society. The seven rules which should govern his relations with the doctor are printed on the back of his medical card in type so inconspicuous that few patients read them even if their eyesight allows them to do so. The rules are sound, and if strictly kept would bring ease to the busy practitioner. "He shall," says rule *e*, "whenever his condition permits, attend at the surgery or place of residence of the practitioner attending him on such days and at such hours as may be appointed by the practitioner." "He shall not," says *f*, "summon the practitioner to visit him between the hours of 6 P.M. and 9 A.M. except in cases of serious emergency." "He shall," ends *g*, "when his condition requires a home visit, give notice to the practitioner, if the circumstances of the case permit, before 10 A.M. on the day in which the visit is required." On the whole insured patients are reasonably good about attending the surgery once they have found their way to it and overcome their initial shyness, but the new class of patient may not appreciate the charms of a chat in the waiting-room. Rules *f* and *g*, too, are more often broken by newcomers than by the old hands who have been well trained by the doctor and know his ways. The unnecessary messages at odd hours which lead to double journeys and make the day's visiting-list unending often arise from misapplied kindness of heart in the patient ("I left it as long as I could, Doctor"), though there is a playful East End habit in an emergency of broadcasting appeals to every doctor within reach, so that three have been known to meet on the doorstep. A nice judgment of what constitutes a "serious emergency" may require more levelheadedness and clinical acumen than the general run of patients or their relatives possess, and while the late evening call may appeal to the dramatic sense it is more likely to originate from panic or a faulty diagnosis than from reckless disregard of the doctor's convenience.

What are the remedies? For the very few who treat the doctor as they do all public servants and demand their rights with no thought for the servant's convenience the doctor can in theory seek redress from the insurance committee, but he rarely does. Nearly all will make as little trouble as they can if they are shown the doctor's point of view. The familiar methods of propaganda could here be effectively applied. The extension of insurance seems a fitting occasion for a "Help your Doctor to help You" campaign, the B.B.C. providing a series of five-minute conversations between doctor and patient and the Ministry of Health supporting them with advertisements in the press. This might, in fact, be made part of the large "Health Front" advocated by Dr. BARBER on another page. The doctor should speak his mind on occasion and he can appeal to the patient's better nature by handbills or posters exhibited in his waiting-room as suggested in these columns last year.[1]

IF YOU WANT TO HELP YOUR DOCTOR IN WAR-TIME

Send messages before 10 A.M. if you want him to visit you. Remember that his petrol is rationed and that his travelling expenses have risen, so he doesn't want to cover the ground twice or more on one day, especially during the blackout.

Avoid night calls and Sunday visits whenever possible.

Come to the surgery if you can, rather than ask for a visit, and come during surgery hours, the earlier the better.

In a message state as clearly as you can what is wrong and how long the patient has been ill. Don't exaggerate or the doctor may have to neglect somebody more seriously ill in order to hurry to you.

Before the war the London insurance committee and some others enclosed in each new medical card a list of Don'ts—e.g., "Don't forget your medical card when you want the doctor." Shortage of paper has suspended this custom, but it might well be revived for the January freshmen, who will respond more heartily to the medical Do-this than to the administrative Don't-do-that. The universal consideration for the doctor which such a campaign might bring would do much this winter to offset the trials of blackout and blitz and the tribulations of a changing population and shorthandedness.

PROBLEMS IN HÆMAGGLUTINATION

Two aspects of agglutination phenomena in blood are receiving current attention; the first is the question of autoagglutination. Few experiences are more disturbing than to be asked to provide blood for the urgent transfusion of a gravely anæmic patient and to find that the patient's serum agglutinates the red cells of all available blood; the patient's serum tested against his own cells will be found to agglutinate these as well—hence the phenomenon is called "autoagglutination." It is due to the presence in the serum of a non-specific, cold-sensitive agglutinin; this affects red blood-cells of all blood groups and is most active below 5° C., still active at room temperature, but as a rule inactive at 37° C. The term "autoagglutination" is now applied only when the effect is seen at room temperature or above. Autoagglutination is often associated with severe anæmia and with disease of the liver. It has not been certainly shown to cause any disease but Mr. BENIANS

A CASE OF PRIMARY OVARIAN PREGNANCY

J N MacBean Ross, M C, M D Edin, F R C S E
SURGEON TO SUTTON AND CHEAM GENERAL HOSPITAL

Pathological findings by T N Gledhill, B A Oxfd, M R C S, PATHOLOGIST IN CHARGE, E M S LABORATORY

THE case published in 1899 by Catherine van Tussenbrock[1] of Amsterdam proved that primary ovarian pregnancy was a definite entity Though it is still regarded as rare a number of cases have since been reported, in recent years particularly in America and Germany The usual course is early rupture of the ovary with only moderate bleeding and the exact diagnosis has as a rule been obscure until operation, though in a few cases the pregnancy goes on to full term and in some gives rise to lithopædion formations In the case here recorded hæmorrhage was extremely severe, the diagnosis of a ruptured ectopic gestation was made with certainty before operation, and there was the added complication of a ruptured corpus luteum hæmatoma

A married woman of 26 was sent by Dr H W Bowen of Carshalton on June 10, 1941, to Sutton and Cheam General Hospital as a surgical emergency During 11 months of married life she had taken no contraceptive measures except very occasional douching She had no child, but in January had probably had a very early abortion No history of previous illnesses or operations Menstruation started at 14 years and was of the 28 day type, it lasted 6 days and was always relatively painless Last menstrual period was stated to have been exactly 4 weeks before admission She had had acute symptoms for 11½ hours prior to admission

She was obviously suffering from a very severe internal hæmorrhage and was in extremis A diagnosis of a ruptured ectopic gestation was made though this was expected to be tubal and not ovarian Arrangements were made for immediate laparotomy combined with continuous blood-transfusion both during the operation and afterwards Gas oxygen ether anæsthesia was administered by Dr J H Willis, and Dr A C Anderson gave the drip transfusion The peritoneal cavity was almost completely full of blood and recent blood-clot The actual amount of blood lost can roughly be estimated by the fact that 18 hours after operation, though she had had 3 pints of blood transfused, the red cells numbered only 2,940,000 per c mm, hæmoglobin 56% When the blood and blood clot had been mopped out as thoroughly and quickly as possible it was seen that fairly brisk hæmorrhage was still coming from a rupture in the right ovary This immediately ceased on applying pressure to the ovarian artery and so the vessel was tied and the ovary removed without difficulty The right fallopian tube was found to be normal and unattached to the ovary, it was therefore left alone The left tube and ovary were normal and the uterus was slightly enlarged The patient returned home on July 3 and is now well She had a menstrual period 28 days after operation and has been regular ever since

Pathological report—The ovary is somewhat enlarged and shows rupture of its surface at two places on the superior border near the upper pole, and on the posterior surface near the lower pole Recent blood clot is present around each site of rupture On section it is clear that the hæmorrhage emanated from two ruptured "cysts" each filled with blood-clot The upper "cyst" is 1 cm in diameter and the lower 1 5 cm in diameter The latter is surrounded by a narrow yellow zone There is no connexion between the cysts Microscopically the lower cyst has the structure of a corpus luteum hæmatoma The upper shows, among the recent blood clot, several chorionic villi, mainly near the site of rupture, and scattered small masses of what appear to be decidual cells This is a ruptured primary ovarian pregnancy associated with a ruptured corpus luteum hæmatoma

Clinically this appeared to be a possible case of primary ovarian pregnancy, though a ruptured Graafian follicle with intra-abdominal hæmorrhage could not be excluded without microscopical examination From a pathological standpoint the literature indicates that to clench the diagnosis chorionic villi must be present, and some experts though not by any means all, also demand the finding of decidual cells but none think the finding of an embryo to be essential, though occasionally it has been isolated from either the blood or the blood-clot effused

Reviews of Books

Medicine versus Invasion

Home Guard Medical Service in Action G B Shirlaw L R C P E, assistant medical officer A R P for Battersea and Clifford Troke, staff officer, Finsbury casualty services London Secker and Warburg Pp 228 7s 6d

READERS have already had a taste of the quality of the book (*Lancet*, Aug 23, 1941, p 225) It is not enough to say of it that all should buy and read it it should be distributed to every Home Guard officer, fighting as well as medical Most people must have thought or wondered just what will be the functions of the Home Guard, the speculation is here given a technical and professional starting-point which is sharply stimulating The first aid section is thoroughly sensible, it is adequate, has no redundancies, and is based on the definition "immediate temporary assistance" The first two sections of the book deal with casualty service tactics and military appreciations The casualty service tactics include the principles of military medicine, the theory of invasion, medical strategy in modern warfare and the part to be played by the Home Guard in town and country Military appreciations include a review of the terrain and descriptions of several hypothetical battles—the battle of Glebeshire, of Barchester, of the Bridgehead and of the Corridor It is these chapters, deliberately drawing a rather dreadful picture of possibilities, which are so important, for unpalatable as the dose may be there is not a single ingredient of which we can say that it might have been left out or that it has been added with an impossibly lavish hand All that is described may happen, and to us "The official view of invasion," say the authors, "is of necessity optimistic (and on the whole justly so), but it is impossible to avoid the suspicion that a nice, neat, comfortable sort of invasion had been pictured and provided for, while the reality will be nasty, untidy and acutely uncomfortable for all concerned"

Diseases of the Nervous System

(2nd ed) F M R Walshe, M D Lond, F R C P Edinburgh E and S Livingstone Pp 325 12s 6d

AN elementary textbook which reaches a second edition within a year has already proved its value Dr Walshe aimed only at producing a simple textbook adapted to the needs of the student and the practitioner, and he was successful because he maintained a delicate balance between the fundamental needs of elementary teaching and the critical selection of material The first edition contained scattered errors of emphasis and statement, of which many have been adjusted, and a number of its briefer sections have been amplified Some clinical photographs and anatomical diagrams have been added, and there is more about the effects of infection and injury upon the central nervous system and peripheral nerves The author's choice of words makes the book a pleasure to read

Roentgen Interpretation

(6th ed) G W Holmes, M D, and H E Ruggles, M D London Henry Kimpton Pp 364 24s

THE sixth edition of this popular book will be welcomed by British radiologists Holmes and Ruggles in their first edition in 1919 did great service by stressing the need for a sound knowledge of pathology and general medicine as a background for accurate radiological interpretation The X-ray diagnosis of bone and joint lesions occupied a large part of the early editions, in those days our knowledge of the radiology of the thorax and abdominal viscera was scanty The study of bones and joints still predominates and occupies half the volume, and there is a 30-page chapter on the spine which is ideal for the student of radiology and indeed the sections on bones and joints maintain this high standard Unfortunately too much has been compressed into the second half of the book The section on the lungs gets 37 pages, that on the heart only 27 and that on the gastro-intestinal tract 44 pages This condensation has led to some dogmatic and unproved statements and we should like the two distinguished American teachers to take more space another time to set out their own experience id had not until recently been given a serious l under controlled conditions McLean[5] at a ic at St Mary's Hospital vaccinated 513 children r a period of 4 years, using three doses of 4000 lion organisms at 3–7 day intervals followed by a rth dose a month later, and he reported no cases of ooping-cough among 46 known and 45 suspected osures, whereas in a control group of 154 children, cases followed 115 exposures Schütze[6] showed erimentally that the combination of diphtheria m-precipitated toxoid and pertussis vaccine had no ibitory action on the immunising property of her antigen, and the idea of combined immunisan, against these two diseases has been gaining ound A single dose of an alum-precipitated rtussis vaccine was given a clinical trial in Maryland S A, in 1936–37, and although the evidence of otection was not such as to justify recommendation the 'one-shot' vaccine there were no severe actions

A large-scale investigation in Norfolk, Virginia was erefore planned to find if two doses of the alumecipitated vaccine at a month's interval would give al protection against pertussis The first report[7] i this investigation is largely concerned with the anning of the experiment so as to obtain (1) an jected group identical in all essentials with a control ninjected group, (2) the uniform observation of both roups over an adequate period of time and (3) a efinition of pertussis as a clinical entity which could e uniformly recognised The difficulties encountered need not be enumerated, the manner in which hey were tackled and largely overcome should be arefully studied by any team of workers likely to ndertake similar field studies in this country Two c cm doses of an alum-precipitated vaccine containing 10 000 million organisms per c cm were njected subcutaneously in the deltoid region of first ne arm and then the other at a month's interval ery few children had any systemic reaction, there as some local tenderness and stiffness, but if the accine was not injected too superficially the firm odule which usually developed was not noticed by the parents After various discards there remained or analysis 641 vaccinated (V) and 571 non-vaccinated N) children, and these were divided into two agegroups according as they were born (A) before and (B) fter July 1, 1937 The table, taken from a larger able illustrating the comparative incidence of measles, hickenpox and mumps in the two groups, shows the cidence of pertussis in vaccinated and unvaccinated hildren before June 1, 1938, when vaccination was egun, and for 34 months after that date The results are not very different from those obtained in their large-scale and carefully controlled experiment by Kendrick and Elderling[8] who used a total of 70 000 million organisms given in four weekly doses, and reported an *annual* attack-rate of 2 3% in the inoculated and 15 1% in the controls As usually happens, it was noted in the Virginia series that pertussis when it did occur in a vaccinated child was milder and of shorter duration than the attack in the uninoculated children These results with alum-precipitated pertussis vaccine should encourage health authorities to combine the pertussis vaccine with diphtheria A P T, in which case it would seem advisable to start the double immunisation during the second six months of life, for at that age pertussis takes a heavy toll of infected children

Age- roup	Vacc (V) for non vacc (N)	Pertussis before June 1, 1938			Pertussis in the 34 months after June 1, 1938		
		No of children	No of cases	Attacked (%)	No of children	No of cases	Attacked (%)
A	V	344	52	15 1	259	29	11 2
	N	304	45	14 8	280	90	39 1
	Total	648	97	15 0	489	119	24 3
B	V	297	17	5 7	234	22	9 4
	N	267	23	8 6	202	60	29 7
	Total	564	40	7 1	436	82	18 8

Passive protection against the infection by the use of human blood or serum has been claimed to be effective (Meader)[9] Using the method of intranasal infection of mice, North and others[10] found that the serum of child convalescents or of immunised children protected against large infecting doses whereas pooled adult serum protected only irregularly against sublethal mouse infections Fortunately pertussis has not the high infectivity of measles or chickenpox when it is introduced into a hospital ward so that the need for passive protection is less urgent But in the home any child under two years who has been exposed to infection might with advantage be given a protective dose of human serum For this purpose panels of immunised donors could with a little organisation be made available

Annotations

THE HEN AS MIDDLEMAN

FOR years we have been taught that as a middleman between vegetable products (particularly grain "offals") and human food the hen, of all domestic animals, is the most wasteful and the cow the least Some publicists even went so far as to give figures for the relative merit of cow pig, bullock and hen, and the hen, as converter of fodder into food, was invariably placed last The cow was reckoned to be five times as efficient as the hen and the pig ranked next to the cow Thus it was considered uneconomical to use offals in producing beef, eggs and fowls (roasters and boilers), and the Government gave priority in feeding stuffs to dairy cows, both in the war of 1914–18 and in the present war and rated hens last It is not clear whether these assessments were based on the total dry constituents produced from (say) 100 lb of fodder, or on the calories or the protein, and it is essential in assessing the efficiency of cow and hen that we should know what we are aiming at It is possible and indeed likely, that the order of merit would need revision if we considered the protein derivable by hen power from a given weight of fodder protein This is clear from a recent article by E T Halnan[11] of the Animal Nutrition Institute at Cambridge Halnan, being an authority on poultry naturally defends the animal of his choice from the obloquy cast on it by agriculturists and dietitians It seems that she has been maligned as a manufacturer of first-class protein from the proteins of lower biological value in offals According to Halnan's estimates the hen converts 100 lb of digestible fodder protein into 31 6 lb and Captain Feasby, who report in this issue the combination of Raynaud's syndrome and autoagglutination, regard them both as caused by chilling in a cold-sensitive patient The blood of outwardly normal people may also show it, an example is provided on another page by Dr Parish and Dr Macfarlane's report of an unusual case in which ionised calcium played a part, and it is noteworthy that, though their patient was an allergic subject with angioneurotic œdema, the autoagglutination was not connected with any allergic attacks Autoagglutination is not common, but among the large numbers of people now being grouped by the transfusion services some are bound to show it, and since the ordinary grouping tests will not detect them the effects of possible misgrouping are worth examination

When blood is taken for the grouping test sufficient plasma is carried over to agglutinate the red cells even in the presence of test sera, the autoagglutinator will therefore be recorded as group AB when in fact he might be any of the other groups If his blood is taken for transfusing a group AB patient unexpected agglutination will take place when his cells are tested against the patient's serum The next step is usually to try another specimen of blood, so that as long as cross-matching is possible no harm will be done, and in emergencies when time does not permit cross-matching group O blood—never group AB—is used If the autoagglutinator's blood is turned into serum or plasma the results are again unlikely to be serious since the abnormal agglutinin is usually inactive at 37° C, and with the large batches of pooled plasma now used the abnormal agglutinin will be much diluted The true group of an autoagglutinator can usually be determined by repeating the tests at 37° C or by washing the red cells in saline before testing If the incorrectly grouped autoagglutinator is himself to receive blood he will be safe so long as cross-matching is properly done, when unexpected agglutination should indicate the necessity for repeating the grouping test at 37° C The drip method is undoubtedly the safest way of giving blood to such a patient The mass-production tactics of the transfusion services make it difficult for every group AB donor to be regrouped using precautions to detect autoagglutinators, and such regrouping is not vital On the other hand, when patients in need of transfusion for severe anæmia are found to be group AB, it is worth while to exclude autoagglutination

The second problem, involving group-specific isoagglutinins, arises in connexion with the use of serum for transfusion Just as the blood-banks store group O blood for emergency use because its red cells contain no agglutinogens, so from a theoretical standpoint group AB serum is the ideal since it contains no agglutinins But only 3–7% of donors are group AB, much of the plasma and serum comes necessarily from the 40–46% of donors who are group O and therefore contains both anti-A and anti-B agglutinins Bryce and Jakobowicz,[1] who made a quantitative examination of a large number of group O sera, found that 31 2% had an anti-A titre and 10 1% an anti-B titre of over 1 in 100 It is generally thought desirable that plasma or serum, especially concentrated serum, should be freed from these isoagglutinins, and the fact that it is more difficult for serum to be so freed has been made a point against its use of group A and group B blood before separating the plasma, so that the A cells absorb the anti A isoagglutinins of group B blood and vice versa, has been one method, but this again limits the donors to about 50% of those available Della Vida and Dyke[2] utilised the fact that agglutinogens are not limited to the red blood-cells but also occur in body fluids including plasma and serum, so that group A serum can be used to absorb the anti-A isoagglutinins of group B serum and vice versa They showed how with group O serum the agglutinin titre could be considerably reduced, even if not completely absorbed, by mixing in suitable proportions with group A and B sera so that the blood of all groups could be used A third method is suggested by Witebsky, Klendshoj and Swanson[3] They point out that the group speci substances (agglutinogens) are complex carbohydrat like bodies resembling the capsular substance of pneumococci Group A substance can be prepared from commercial pepsin, mucin or peptone, but group B substance has so far only been isolated from the gastric juice of group B persons By adding these two group-specific substances to group O blood they are able to reduce the titre of the anti A and anti B agglutinins in the plasma to a safe level This method is an interesting application of our increasing knowlegdge of the nature of the blood groups but is hardly suitable as yet for large-scale work Clinical reports of reactions after the transfusion of group O serum into patients of other groups are scanty, and it is not yet clear how far the presence of anti A and anti B isoagglutinins is really detrimental The definition of safe limits for the titres of these agglutinins in pooled serum should not be too difficult and would provide the transfusion services with a useful standard

PERTUSSIS PROPHYLAXIS

The present prevalence of whooping-cough remind us how little has been attempted in this country towards the prevention of this preventable disease Too many of us still regard pertussis and measles as the inescapable and not very serious afflictions of childhood But in London these two rank fourth and fifth among the causes of death in children under five years, and in hospital practice the case-fatality from pertussis exceeds that of both measles and diphtheria (L C C Annual Report, 1935) Moreover, about a tenth of the cases and two-fifths of the deaths from pertussis occur in the first year of life[4] while Stock estimated that 44% of London children developed the disease before their fifth birthday Prophylaxis of so prevalent a respiratory infection could only be possible by specific vaccination, and this method of prevention has been shown, particularly in America to be a practical possibility Unfortunately, four or five weekly injections of large doses (10–30 thousand million organisms) of a carefully prepared smooth phase vaccine are apparently necessary to secure an effective immunity, which for large-scale immunisation introduces serious problems in production and administration The possibility of protecting the child by fewer doses of the vaccine spaced at longer intervals, as has been proved effective with diphtheria is diagnosis seems hardly warranted, the sensation ing typical neither of effort angina nor of infarction gina With the collapse, cold extremities and brady- rdia which may accompany the thoracic distress the cture seems identical with that of the vasovagal attack Gowers s syndrome This is presumably what Zondek fers to when he mentions "angina pectoris vaso- otoria" as entering into the differential diagnosis of is cases A therapeutic test with thyroid extract is commended for confirming the diagnosis and while this valuable it should not be forgotten that thyroid extract ay be of help in some conditions other than hypo- hyroidism through one or more of the physiological ctions of the hormone Two other signs described by ondek are narrowing of the skin capillaries and enlarge- ent of the left ventricle, though only one of the three ases described showed this enlargement and this patient ad systolic murmurs in all areas The effects of thyroid eficiency deserve closer study, especially in its mild orms, and a critical examination of Zondek s cases shows ow difficult the diagnosis may be The thoracic distress n these cases is usually of a type which does not permit he diagnosis of angina pectoris but when cardiac pain s encountered in frank myxœdema it is essential that hyroid extract be given with caution This is especially if there is reason to think that cardiac infarction has urred The initial dose of the extract should not eed gr ½ daily and the effect should be observed for east a week before increasing it Any aggravation he pain would of course demand a reduced dose or plete withdrawal of the drug

HEALTH OF GERMAN TROOPS IN FRANCE

N a lecture given to German army doctors in Nancy the spring of this year, Gänsslen[1] reviews the health one of the German armies during the preceding 9 nths The general sickness-rate was low, this was ributed partly to favourable weather and partly to unexpectedly rapid conclusion of the French cam- ign, which allowed the troops to settle soon into arters almost as comfortable as those of peace time e chief epidemic diseases were those of the alimentary ct Outbreaks of gastro-enteritis occurred often ceable to contaminated food, sometimes organisms the salmonella group were responsible, but in the most pandemic outbreak in the summer of 1940 cteriological investigation was inconclusive Dysen- ry occurred fairly often, usually in mild form Flexner s cillus being commonest and Shiga s rare Two small nical points in its recognition are noted that labial rpes, occurring in 20–30% of cases of non-dysenteric stro enteritis, is rare in dysentery, and that 'to him ho has a fine nose the stale semen-like smell of the stool ll suggest dysentery' Among the sequels of dysen- ry the familiar arthritis was met with, arising in almost y joint, and attention is drawn to urethritis and con- nctivitis, both of which are naturally liable to be attri- ited to other causes A controlled observation of the fect of anti dysentery serum on alternate cases (Shiga fections being excluded) showed that it had no clear eneficial action Hypertonic saline given intravenously nd blood-transfusions were valuable measures in the verest cases A trial of sulphanilamide was begun but ot concluded Dysentery was largely confined to the w-lying or flat country in northern France and landers, from the troops and prison camps in the well- ained, more thinly populated uplands of the Vosges was almost absent The German army in question as apparently not free from enteric fever, though cases ere not numerous, paratyphoid occurred oftener than phoid No mention is made of the extent of preventive oculation Small epidemics of catarrhal jaundice curred without ascertainable cause Cerebrospinal ver reached the peak of its incidence in the spring, and then almost subsided, its fatality was probably under 20% Sulphanilamide or its derivatives is credited with influencing the severity and mortality of the disease, but Gänsslen is surprisingly lukewarm in his approval of it There is no mention of chronic meningococcal septicæmia A small outbreak of zinc poisoning —not new to the Germans, who had already experienced it on the Westwall—with acute gastro intestinal symptoms was caused by the preparation and serving of salads in zinc vessels

MIDDLE-CLASS PROVIDENCE

THERE is a wide gap between even a heavy bill from a family doctor and the cost of a serious illness or operation involving nursing-home and surgeon s fees, and many people with moderate incomes who are well able to pay for ordinary medical treatment are stumped when faced with an expensive emergency Since 1921 the British Provident Association has been tempering the wind to these semi-shorn sheep lately Bristol has launched its Intermediate Contributory Scheme for them, King Edward s Hospital Fund is sponsoring a provident scheme for London,[1] and now Lord Nuffield has given £150,000 to set up a Provident Guarantee Fund to encourage the formation of many more insurance schemes of this kind The new fund will guarantee the solvency of contributory schemes set up in the provinces in Scotland and in Northern Ireland to cover the cost of specialists and surgical treatment in hospital pay-beds and nursing-homes for the middle and professional classes It is hoped that these provincial schemes will work alongside the hospital councils with which the Nuffield Provincial Trust is associated The guarantee will be conditional on the scheme s approval by the trustees of the fund and this benevolent supervision will enable the associations to offer their members a uniformity of benefit and facilities for transfer which are unusual in local enterprises The address of the fund is 16, King Edward Street, Oxford

ECONOMY IN PHENOL AND ASPIRIN

THERE is need for economy in phenol and certain allied substances which have so far been readily available In a circular letter to hospitals and medical officers of health the Ministry of Health asks that phenol salicylic acid acetylsalicylic acid, sodium and methyl salicylate and phenolphthalein should be used sparingly It should not be difficult to devise substitutes for carbolic acid itself and for phenolphthalein but the salicylates and especially aspirin, will be difficult to cut down To be fully effective an appeal for reduction in the consumption of aspirin will have to be made to the public direct, for only a small proportion is now sold on prescription Nothing will presumably be gained by giving phenacetin or phenazone instead, for these are also derivatives of phenol Doctors can no doubt help by prescribing aspirin and the salicylates only when there is a definite indication for them, and where aspirin must be given repeatedly it may be found that a smaller dose suspended with tragacanth is as effective as a larger in tablet form

PECTIN AS A BLOOD SUBSTITUTE

THE provision of enough whole blood and serum or plasma for use in shock or hæmorrhage is not always easy, and new materials are being tried out as substitutes Of the older substitutes, gum acacia accumulates in the liver and may depress protein regeneration, while gelatin is antigenic More recently isinglass has been used with success,[2] but this awaits confirmation Meanwhile Hartman and his associates[3] suggest pectin solution

; diagnosis seems hardly warranted, the sensation ag typical neither of effort angina nor of infarction gina With the collapse, cold extremities and brady-dia which may accompany the thoracic distress the ture seems identical with that of the vasovagal attack Gowers's syndrome This is presumably what Zondek ers to when he mentions "angina pectoris vaso-toria" as entering into the differential diagnosis of ; cases A therapeutic test with thyroid extract is commended for confirming the diagnosis and while this valuable it should not be forgotten that thyroid extract ay be of help in some conditions other than hypo-yroidism through one or more of the physiological tions of the hormone Two other signs described by ndek are narrowing of the skin capillaries and enlarge-ent of the left ventricle, though only one of the three ses described showed this enlargement and this patient d systolic murmurs in all areas The effects of thyroid ficiency deserve closer study, especially in its mild rms, and a critical examination of Zondek's cases shows w difficult the diagnosis may be The thoracic distress these cases is usually of a type which does not permit e diagnosis of angina pectoris, but when cardiac pain encountered in frank myxœdema it is essential that yroid extract be given with caution This is especially if there is reason to think that cardiac infarction has ccurred The initial dose of the extract should not xceed gr $\frac{1}{4}$ daily and the effect should be observed for t least a week before increasing it Any aggravation f the pain would of course demand a reduced dose or omplete withdrawal of the drug

HEALTH OF GERMAN TROOPS IN FRANCE

IN a lecture given to German army doctors in Nancy n the spring of this year, Gansslen[1] reviews the health f one of the German armies during the preceding 9 nonths The general sickness rate was low, this was ttributed partly to favourable weather and partly to he unexpectedly rapid conclusion of the French cam-paign, which allowed the troops to settle soon into uarters almost as comfortable as those of peace-time The chief epidemic diseases were those of the alimentary ract Outbreaks of gastro enteritis occurred, often raceable to contaminated food, sometimes organisms f the salmonella group were responsible, but in the lmost pandemic outbreak in the summer of 1940 acteriological investigation was inconclusive Dysen-ery occurred fairly often, usually in mild form, Flexner's acillus being commonest and Shiga's rare Two small linical points in its recognition are noted that labial erpes, occurring in 20–30% of cases of non-dysenteric astro enteritis, is rare in dysentery, and that "to him ho has a fine nose the stale semen like smell of the stool ill suggest dysentery" Among the sequels of dysen-ery the familiar arthritis was met with, arising in almost ny joint, and attention is drawn to urethritis and con-unctivitis, both of which are naturally liable to be attri-uted to other causes A controlled observation of the ffect of anti dysentery serum on alternate cases (Shiga ifections being excluded) showed that it had no clear eneficial action Hypertonic saline given intravenously nd blood transfusions were valuable measures in the everest cases A trial of sulphanilamide was begun but ot concluded Dysentery was largely confined to the ow-lying or flat country in northern France and landers, from the troops and prison camps in the well-rained, more thinly populated uplands of the Vosges was almost absent The German army in question as apparently not free from enteric fever, though cases ere not numerous, paratyphoid occurred oftener than phoid No mention is made of the extent of preventive oculation Small epidemics of catarrhal jaundice curred without ascertainable cause Cerebrospinal ver reached the peak of its incidence in the spring, and then almost subsided, its fatality was probably under 20% Sulphanilamide or its derivatives is credited with influencing the severity and mortality of the disease, but Gänsslen is surprisingly lukewarm in his approval of it There is no mention of chronic meningo-coccal septicæmia A small outbreak of zinc poisoning —not new to the Germans, who had already experienced it on the Westwall—with acute gastro-intestinal symp-toms was caused by the preparation and serving of salads in zinc vessels

MIDDLE-CLASS PROVIDENCE

THERE is a wide gap between even a heavy bill from a family doctor and the cost of a serious illness or opera-tion involving nursing-home and surgeon's fees, and many people with moderate incomes who are well able to pay for ordinary medical treatment are stumped when faced with an expensive emergency Since 1921 the British Provident Association has been tempering the wind to these semi-shorn sheep, lately Bristol has launched its Intermediate Contributory Scheme for them, King Edward's Hospital Fund is sponsoring a provident scheme for London,[1] and now Lord Nuffield has given £150,000 to set up a Provident Guarantee Fund to encourage the formation of many more insurance schemes of this kind The new fund will guarantee the solvency of contributory schemes set up in the provinces, in Scotland, and in Northern Ireland to cover the cost of specialists and surgical treatment in hospital pay-beds and nursing homes for the middle and professional classes It is hoped that these provincial schemes will work alongside the hospital councils with which the Nuffield Provincial Trust is associated The guarantee will be conditional on the scheme's approval by the trustees of the fund, and this benevolent supervision will enable the associations to offer their members a uniformity of benefit and facilities for transfer which are unusual in local enterprises The address of the fund is 16, King Edward Street, Oxford

ECONOMY IN PHENOL AND ASPIRIN

THERE is need for economy in phenol and certain allied substances which have so far been readily available In a circular letter to hospitals and medical officers of health the Ministry of Health asks that phenol, salicylic acid, acetylsalicylic acid, sodium and methyl salicylate and phenolphthalein should be used sparingly It should not be difficult to devise substitutes for carbolic acid itself and for phenolphthalein, but the salicylates, and especially aspirin, will be difficult to cut down To be fully effective an appeal for reduction in the con-sumption of aspirin will have to be made to the public direct, for only a small proportion is now sold on pre-scription Nothing will presumably be gained by giving phenacetin or phenazone instead, for these are also derivatives of phenol Doctors can no doubt help by prescribing aspirin and the salicylates only when there is a definite indication for them, and where aspirin must be given repeatedly it may be found that a smaller dose suspended with tragacanth is as effective as a larger in tablet form

PECTIN AS A BLOOD SUBSTITUTE

THE provision of enough whole blood and serum or plasma for use in shock or hæmorrhage is not always easy, and new materials are being tried out as substitutes Of the older substitutes, gum acacia accumulates in the liver and may depress protein regeneration, while gelatin is antigenic More recently isinglass has been used with success,[2] but this awaits confirmation Meanwhile Hartman and his associates[3] suggest pectin solution

Its advantage, apart from ease in preparation, is that a 0·5% solution has about the same viscosity and osmotic pressure as whole blood. A simple solution is too acid and requires buffering to the correct pH. Good results were obtained in animal experiments and the substance was found not to be antigenic, neither did it depress liver function. Preliminary trials on human subjects showed that it was capable of raising the blood-pressure in shock and the rise was maintained during the time of the experiment. Though pectin is retained for a short time in the blood and liver it is rapidly excreted by the kidneys. It remains to be seen whether it will stay in the circulation long enough to overcome all tendency to shock.

SULPHADIAZINE AND SULPHONAMIDE E O S

THE observant physician has been learning in the past few years when and how to use each of the available sulphonamide compounds to the best advantage of the patient—sulphanilamide for streptococcal and coliform infections, sulphapyridine for pneumococcal, sulphathiazole for staphylococcal, and one of the last two for meningococcal and gonococcal infections. But many doctors are not so discriminating, and use sulphanilamide or sulphapyridine for all manner of infections without regard to the fact that the treatment may be more harmful than the malady. Sulphapyridine in particular needs to be used with care for not only may it upset the patient's stomach and appetite but it also tends to form crystals in the urinary tract unless the fluid intake is liberal, a tendency which it shares with sulphathiazole. Again, these drugs are often given in inadequate doses, and if this practice continues we may be faced with drug-fast strains of the common pathogens and infections which are entirely resistant to sulphonamide therapy. Sulphathiazole seemed to have advantages over the earlier preparations, being effective against most of the pathogens and much less irritating to the stomach than sulphapyridine. It has two disadvantages, however, for it is very quickly excreted, so that a high concentration in the blood is difficult to maintain and at present supplies are limited.

The maintenance of an adequate blood level of the drug chosen without too frequent dosage (ill patients should not have to be wakened in the middle of the night) is most important, and sulphadiazine, the pyrimidine analogue of sulphapyridine, is endowed with the valuable property of producing a higher sustained blood-level than sulphapyridine and sulphathiazole[1] with the same dosage. Moreover, it does not easily upset the stomach, and apparently is not concentrated in the kidney, as sulphapyridine and sulphathiazole are, so that there is less risk of kidney damage. Finland, Strauss and Peterson[2] have lately reported the results obtained with sulphadiazine in a variety of clinical infections among 446 adults. In the largest group of 316 cases of pneumonia there were 178 cases of primary pneumococcal pneumonia, of whom 19 (10·7%) died, which may be compared with a fatality of 16·3% among 687 patients treated the previous year with sulphapyridine or sulphathiazole with or without specific antiserum. Of the 19 patients who died, 8 were moribund on admission and 9 of the others were old people who died after the pneumonic infection had apparently been overcome. Complications were relatively few and three-quarters of those who recovered were afebrile within 36 hours of beginning treatment. There were 29 cases of staphylococcal pneumonia, occurring mostly as a complication of influenza. Some of these responded promptly to sulphadiazine, others ran a more chronic course with abscess formation and pleural effusion, 6 of them died. The usual course for adult patients with pneumonia was an initial dose of 2–4 g follow 1 g 4-hourly until the patient had been afebrile for days, which usually meant treatment for 6 days with total dosage of 40 g or less.[2] Finland and his co thought the results compared favourably with th obtained with the earlier sulphonamide preparation with serum. They were also impressed with the ef of the drug in tonsillitis, erysipelas and acute, but chronic, urinary infections. Their 4 cases of pn coccal meningitis treated with the drug all died. T symptoms were of the kind which other drugs of sulphonamide series produce but were on the whole and infrequent. One patient developed ureteric with hæmaturia followed by anuria which was relieved ureteral catheterisation. Sulphadiazine was also used w good results by Dingle, Thomas and Morton[3] in the ment of 13 cases of meningococcal meningitis and 1 c of meningococcal septicæmia. 1 patient with mening died ten hours after admission. Dowling and others[4] employed much the same dosage as Finland in the 115 patients with pneumococcal pneumonia, thou lately they have raised the initial dose from 2 g to 4 or even 6 g. In their whole series the fatality was 11·3%—the same figure as in their previous series on sulphapyridine, but it was only 6·3% in the 64 patient in whom sulphadiazine was begun within the first four days. Serum in addition was given in 16 older patients, of whom 2 died. Toxic effects were very slight, and never made it necessary *to stop* giving the drug by mouth.

Mutch[5] has lately described his experience with sulphonamide ethyl-σ-sulphonate, prepared by Imperial Chemical Industries. This compound is freely soluble in water, is of low toxicity and is hydrolysed in the body with the liberation of sulphanilamide. Mutch has used it in a variety of infections and he reports a representative series of 34 cases of meningococcal meningitis with a fatality of 9% and few unpleasant side effects. The molecular weight of Sulphonamide E O S is nearly twice that of sulphanilamide, so that larger doses must be given, but Mutch suggests that since it can be administered in an almost tasteless solution it may prove particularly useful for infants and fastidious, vomiting or comatose patients.

HEALTH OF THE INDUSTRIAL COMMUNITY

IN years to come 1940 will count as a significant c in the long struggle for improved labour conditions. War has acted as a catalyst and brought about large scale organic changes which in peace time would have seemed impossible. It would be facile to call these changes a bloodless revolution, for there was at the same time an increase in industrial accidents as well as an intensification of aerial bombardment of the industrial towns. One side of this great story can be read in the annual report of the Chief Inspector of Factories summarised on another page. The report which has l its familiar blue cover and its statistical tables contains an account of all the important developments during the year leading to improved welfare conditions, the term "welfare" being used in a broad sense to connote not only the comfort but also the well-being of the workers and to include measures to prevent accidents and to maintain health. As far as it goes the report is satisfying, but medical readers will regret the omission of anything helpful about industrial diseases and poisonings, which is peculiarly unfortunate when so many of them are facing for the first time some of the major problems of factory life. Steps should be taken to circulate a fuller version of Dr J C Bridge's report among the doctors whom it so closely concerns.

TOWARDS A NATIONAL SERVICE IN CLINICAL PATHOLOGY

S C DYKE, D M OXFD, F R C P
DIRECTOR OF THE PATHOLOGICAL DEPARTMENT, THE ROYAL HOSPITAL, WOLVERHAMPTON

THE present war must bring about great changes in the organisation and practice of medicine in this country, and by general consent many changes are long overdue In face of this prospect it is the business of all those interested to take counsel with a view to directing developments into proper channels Not least important is the place of pathology and the function to be filled by laboratories and laboratory workers

The standard of academic teaching and research maintained by the medical schools and research institutions of this country is high, but clinical practice has for more than a generation been slow in embodying the full possibilities of laboratory work Only recently pathology, bacteriology and biochemistry and their allied studies were being referred to as "ancillary" to clinical medicine The war of 1914–18 revealed a similar schism between the clinical practice of medicine and its basic sciences in this country, and clinical units were established in certain of the London teaching hospitals to restore unity within the body of medicine How far the gap still remains open can be judged by all who have been in contact with the graduates of the medical schools over the last twenty years The clinician by the bedside may now ask for more laboratory tests than his predecessor of a generation ago, but increasing demands on his time make it difficult for him to keep sufficiently in touch with the many possible lines of investigation to enable him to select the most appropriate and gauge correctly the values to be attached to the bare results of laboratory procedures The laboratory worker on his side has often chosen this branch of medicine because of lack of interest in the clinical side Purely academic research, in the long run of deep importance, has been and will continue to be done by workers not interested in and divorced from clinical medicine, but for the immediate treatment of the sick there is required a body of medical men and women fully acquainted with all the details of laboratory technique in its application to clinical medicine, and interested equally both in clinical and laboratory work Only those so trained and equipped are in a position to direct, or help to direct, both the laboratory investigation of clinical problems and the interpretation of results

The field to be covered by such workers may for lack of a better term be described as clinical pathology This term has been regarded with some disfavour in academic circles in this country, partly because it is something of a hybrid including all the basic sciences of medicine which form, in academic institutions, the subjects of separate departments or even professorial chairs, and partly because of the misguided activities of some of its earlier practitioners

THE PLACE TO BE FILLED

Clinical pathologists are now attached to all the larger non-teaching hospitals and even before the war the demand was increasing, the development of the E M S hospital service has led to a call for many more than are now available and inducements are being offered to promising young medical men and women to take up this branch of work The E M S is a living and growing concern and it is clear that it cannot remain merely "emergency", it is developing and will continue to develop as an integral part of the nation's medical service and in so doing must profoundly affect the whole future of medical practice It is proper at this time to consider the role of clinical pathology in the nation's medical organisation, and the future status of its practitioners Naturally it can only properly be practised by those in close and continuing touch with clinical medicine From this it follows that its seat must be in laboratories forming an integral part of large and active hospitals Neither the laboratory established by a local authority for the purpose of dealing with public health pathology and bacteriology, the university laboratory maintained for the purpose of teaching and research, nor the isolated laboratory of any sort is fitted for the proper pursuit of clinical pathology It can only function efficiently in a laboratory which is part of an institution for the care of the sick

Clinical pathology must, then, be closely bound to the national hospital service, in the E M S it is already so bound It is evident that the national hospital service is even now entering on a phase of rapid evolutionary change and it seems likely that this change will proceed along the lines of regionalisation The British Hospitals Association has long been working for the regional grouping of the voluntary hospitals, for E M S purposes such regional grouping of hospitals is already in being, the work of the Nuffield Provincial Hospitals Trust is, with the support of the Minister of Health, already beginning to make itself felt, and there is reason to hope that there will in due course appear a hospital service calculated to meet all the hospital requirements of the nation and including without distinction all hospitals—voluntary (both teaching and non-teaching) and municipal The country will for hospital purposes be divided into a number of regions and these again into divisions, each centring round a key hospital Most of the regions will contain a teaching hospital, this will serve as the key hospital of its own division and should occupy a unique position among the key hospitals of the whole region Its position, however, must depend on its own merits and be that of "primus inter pares" rather than one of unquestioned supremacy All key hospitals will require their own departments of clinical pathology and around these will centre the work of their divisions, including work for the hospital itself and for the area covered by the hospital

The proper functioning of the clinical pathological department of an active hospital must bring it into contact with every department of the clinical work of the hospital It should not merely be a place where specimens are examined and reports on them issued The place of the clinical pathologist is in the wards as well as in the laboratory It is his business in consultation with the clinical staff to assist in determining the lines to be pursued in the investigation of clinical problems and the interpretation of results Much of the work at the bench must be performed by skilled technicians, but it is his duty to see that it is properly done, and it is he who must introduce new techniques as they become available and generally see that the work of his laboratory is kept at a due pitch of efficiency, and he must ensure that full and proper use is made of the facilities of his department This entails close touch with the clinical staff He must also be vigilant against the clogging of the laboratory by specimens sent down as a matter of unthinking routine, the examination of which can have no real bearing on investigation or treatment

A DOMICILIARY SERVICE

The needs of the division, apart from those of the hospital, can to some extent be met by the delivery at the laboratory of specimens for examination Such an impersonal service, however, can no more meet the needs of the community as a whole than it can that of the hospital The clinical pathologist must be available in person to assist, in consultation, in the investigation of clinical problems outside as well as inside the hospital The clinical pathological service must be domiciliary as well as institutional As matters now stand such domiciliary consultations with the clinical pathologist are available only to those in a position to pay consultants' fees A national service must minister to the needs of the whole community, not excluding its less prosperous members The provision of such a domiciliary service offers no insuperable difficulties The details of its constitution may well differ from region to region and from division to division In some key hospitals certain of the clinical pathological staff might elect to serve on a part-time basis, devoting some of their time to private practice, these might possibly be those sojourning only temporarily in the service with the intention of proceeding later to purely clinical work Alternatively the domiciliary work might be undertaken by the whole-time staff and the fees accruing from it be placed to the credit of the service There are advantages and disadvantages in both systems and it would be desirable that for a time both should work side by side, the course of events would show the system most worthy of adoption Early standardisation is not desirable and might prove never to be desirable events might well show the same system not to be equally suitable to all areas

Any hasty and ill-considered attempt to impose a rigid uniformity on the clinical pathological (as on any other) part of the national hospital service would be disastrous The national hospital service even as now existing offers one of the best examples of our traditional genius for devising and maintaining locally institutions suited to local needs It is accepted that the national hospital service must receive financial assistance from the state and the acceptance of financial assistance naturally carries with it certain obligations, the fulfilment of these obligations must not entail the sacrifice of local effort and initiative and its replacement by bureaucratic rule It is a wise saying that "it is an injustice a grave evil and a disturbance of right order for a larger and higher organisation to arrogate to itself functions which can be efficiently performed by smaller and lower bodies" The national hospital service of the future must allow to its component hospitals a degree of autonomy subject only to the general direction of divisional and regional hospital councils, on both of which the hospitals should be able to make their voices heard

CLINICAL PATHOLOGY AND PUBLIC HEALTH

Clinical pathology must necessarily have contacts with what is usually described as public-health pathology The concern of clinical pathology is the individual case and that of public-health pathology the community as a whole The two spheres impinge on each other and it is neither possible nor desirable to draw any exact frontier between the two Much confusion has resulted from the habit of regarding the sphere of public health as comprising anything ordained or governed by administrative statutes Because there is a statutory obligation on local authorities to arrange for the examination of throat swabs for diphtheria this is regarded as coming within the scope of public health It may and usually does so, but it also falls within the sphere of clinical pathology The same thing applies to all forms of examinations in connexion with disease epidemic or likely to become so From the standpoint of the individual patient these examinations fall within the scope of clinical pathology, from the standpoint of the epidemiologist they fall within the scope of public-health pathology

The matter is further complicated by the fact that the laboratories of many hospitals throughout the country undertake the public-health work for their areas This is not the primary business of the hospital laboratory but the work brings much-needed financial assistance to the laboratory—in many cases it is its main source of income, without which it would never have been established and could not be maintained Under the regionalised system envisaged by the Nuffield Trust the hospital would be free of the necessity of seeking extraneous sources of income for the maintenance of its laboratory The laboratory and its service would become a part of the regional (and through it of the national) hospital service and would be in a position to extend its full energies within its proper field of clinical pathology

With the development of municipal hospitals, local authorities have found themselves under the necessity of arranging for much pathological work for individual patients in their charge, because performed under statutory sanction or obligation this work has also come to be regarded as falling within the definition of public health The fact that it is performed under statutory sanction, however, does not alter the fact that such work for hospital patients falls within the scope of clinical and not of public-health pathology In many instances local authorities have established laboratories in the hospitals under their charge This is the right and proper course, such hospitals with their laboratories occupy a place in the hospital service of their region In other areas, in which local authorities have in the past established central laboratories for dealing with the pathology and bacteriology of epidemic disease, the clinical pathology of all the municipal hospitals has centred on these laboratories This entails the port of specimens from the hospitals to the c laboratory, and renders impossible that close and tinuing touch with clinical work on the part of the laboratory staff essential for the proper practice clinical pathology These central laboratories have an important function to fulfil in the national medical service that function, in fact, for which they were established—to deal with the mass control of epidemic diseases At present their work is largely confined within their own walls Measures for the full control and investigation of epidemic disease must extend into the field, and must take the staff outside the laboratory into the hospitals and the homes of the people, not primarily for the purpose of investigating the individual case but to control the spread of epidemic disease The field laboratory unit until lately did not exist in this country Some are now fully embodied and others exist in a skeleton form, workers in one such unit have testified to me with enthusiasm about the value and the interest of the work In such units the public health pathologist and the clinical pathologist must work side by side, but the control of such units would fall to the central public-health laboratory of the region concerned

PERSONNEL

The clinical pathological service must be the concern of the key hospital, among these will be both those with and without medical schools In addition to their other functions the departments of the teaching hospitals will be concerned also with the teaching of students, their staffs will on this account require to be larger than those of non-teaching hospitals

In the medical schools of teaching key hospitals there may be departments of pathology, bacteriology and biochemistry each under the direction of a separate head and each with its own laboratories The existence of such departments, whether separately or under one head, will not obviate the need for a hospital department of clinical pathology under its own director Whether in teaching or non-teaching hospital the director will require to be one of sound clinical training, well grounded in physiology and thoroughly acquainted with all branches of laboratory work in relation to clinical medicine, though not necessarily equally adept in all The director of clinical pathology in a teaching hospital will have the immense advantage of ready access for assistance and advice to the staff of the academic departments, and such posts will naturally attract the best workers in the field In both teaching and non-teaching hospitals the director will require the assistance of a staff varying in size with the size and activity of the department

From the assistants in the department of key hospital will be drawn the future directors of the national hospital laboratory service Not every medical graduate has that taste and aptitude for the combination of clinical and laboratory work which must go to the vocation to clinical pathology No assistant should be admitted to the staff of the department of clinical pathology until he or she has done at least one year in house posts, in the course of which evidence of the vocation should have shown itself A period as assistant in the laborator of one or more of the special departments of a teachi key hospital would be a valuable part of the training of the assistant clinical pathologist, this period might be taken at any time after he had done his resident hou course, preferably after a term of apprenticeship as junio assistant in the department of clinical pathology, b it should by no means serve as a substitute for such a junior assistantship

The most junior assistants in the department of clinical pathology would be on the same footing as the resident house-officers For one year at least, and possibly longer, they should live in the hospital This is essential for the sake of both the hospital and the officer for the hospital because the services of the hospital must be available throughout the twenty-four hours, and for the officer because by living in the hospital as a member of the residents' mess he can best attain that close and continuing touch with clinical medicine which is so necessary a part of his training While resident the salary and emoluments of the assistant clinical pathologist uld be at the same rate as that of other house-officers comparable seniority and such posts would be whole-ne

The remuneration of the heads and non-resident sistants of the clinical pathological staffs of the key spitals remains to be determined As things are, the nical pathologist attached to a voluntary hospital epends partly on remuneration by the hospital and rtly on private work The remuneration from the ospital may be financial or may take the form of the ght to use the hospital laboratory for private work, or oth In the municipal hospitals the post of pathologist usually salaried, pensionable and whole-time There something to be said for and against both systems f remuneration For partial remuneration with the ght to private practice it can be urged that this system nables the hospital to get the services of a pathologist nore cheaply than if it had to pay in salary his full narket value, under a regionalised hospital system ith financial assistance from the state this argument vould largely lose its cogency But the contacts with atients and medical practitioners attained in the course f private practice are valuable in the development of he pathologist Against the system is the objection hat where the treasure is there will the heart be also, nd that the temptations of private practice may seduce he pathologist into neglecting his hospital work The alaried whole-time system makes it possible for the athologist to give the whole of his time and energies o the work of his hospital It suffers from the disadvantage that whole-time posts may attract the unambitious and unenterprising, and that even the most promising once ensconced in a safe job with reasonable salary and the sure and certain hope of a comfortable pension may lapse into lethargy and desuetude Ideally it should be possible to devise a system under which merit would ensure advancement and its absence elimination, but experience shows how difficult this may be under the terms of human institutions

Advocates of both systems of remuneration are to be found among clinical pathologists of all degrees of experience and seniority Granting that the terms of remuneration are reasonable I have heard both senior workers of long and varied experience and juniors only recently entered on the field unite to speak in favour of a whole-time service The subject calls for wide discussion and exchange of views Good work has been and can be done under both systems and a hasty decision in favour of the universal application of either would be highly undesirable Arrangements suitable to one type of hospital or to one group of hospitals are not necessarily so to all

Under a regionalised hospital service clinical pathology would form part of the regional and national hospital services Under a system of modified individual autonomy on the part of the key hospitals the terms of employment offered to clinical pathologists by individual hospitals might, at any rate in the earlier stages of development of the system, differ to some extent The most desirable terms would in time become apparent The establishment of clinical pathology within the national hospital service would make this branch of medicine far more attractive to future generations of medical men and women Up to the present the beginner, n attaching himself to a non-teaching hospital, has ad to face the realisation that in so doing he has stablished himself in a post from which there is little ikelihood of his translation In a regionalised national ervice the beginner would be starting at the foot of a adder which might bring him eventually to the highest places in the national service Further, instead of aving to work in comparative isolation the clinical athologist attached to a key hospital would be in a position to maintain constant touch with other workers n his region, to specialise in any subject of particular nterest to himself, to assist others in this and to receive rom others help and advice in their own specialties

Such a national service in clinical pathology could not ail to become a great force in the advancement of medicine The need for it is shown by the repeated epresentations of practitioners under the National Health Insurance Acts for the inclusion of facilities for aboratory investigations in the panel benefit, and by imilar demands by the British Medical Association That the need has not before now become so apparent and urgent as to force Governmental action is due to the efforts of the voluntary hospitals which have made a partial service available through their outpatient departments It is right that further developments should continue along these lines with the national service in clinical pathology embodied in the national hospital service In the development of both it is essential for safety to steer a course between over-centralisation and laissez faire For development to proceed along the proper channels guidance must come not by edict from above but through the united effort of all those concerned

---

MEDICINE AND THE LAW

Refusing Consent to Amputation

A PARENT who " wilfully neglects " a child by failing to provide adequate medical aid commits a misdemeanour It was held in Oakey *v* Jackson in 1914 that the refusal to allow an operation for adenoids might amount to neglect Recently a father was indicted at Glamorgan quarter sessions for neglecting his six-year-old son (who was suffering from tuberculosis of the left knee) by refusing to allow amputation of the limb (R *v* Imms) The prosecution offered medical evidence that, while the operation might prove fatal, the boy would die if no operation was performed Dr Alex Brownlee medical superintendent of the Glan Ely hospital, gave the history of the case The patient had been most carefully nursed for 14 months, he was able to walk when he was discharged Last April, however, he was readmitted to hospital His condition was progressively deteriorating; he was beginning to suffer from chronic poisoning of the system due to the diseased knee " If the life of the child is to be saved " said the witness, " this amputation should be performed " It was impossible to save the limb, operation was the only hope of saving the boy's life, the patient's condition was becoming so serious that it would soon be too late to operate. ' I think he will die if it is not done " A consulting surgeon confirmed this view The father explained that he refused because he was afraid that the shock of the amputation would kill his boy; even if he recovered, he would be a cripple for life, " if I consented to the amputation and Terence died, I should have signed his death warrant, if I thought he would recover, I would consent at once " His counsel took the points that the father had never been told of the boy's life being in danger and that the refusal was not absolute—not " I will never consent " but merely " I will not consent at this stage ' The jury returned a verdict of " not guilty " without leaving the box

After a long series of enactments and re-enactments the law is now to be found in section 1 of the Children and Young Persons Act, 1933 Judges have construed " wilfully " as done deliberately and not by inadvertence " neglect " as the absence of such reasonable care as an ordinary parent would reasonably use for the care and protection of the child So said Lord Russell of Killowen in R *v* Senior (1899) where a nine-months-old infant died of diarrhœa and pneumonia and the prosecution proved that life would certainly have been prolonged and in all probability saved if medical assistance had been provided R *v* Morby (1882) where the child suffered from confluent smallpox, had shown that the parent could not be convicted unless it was proved that death was caused or accelerated by the omission to call in medical aid Subsequent prosecutions of persons holding the faith of the Peculiar People, who refused to call in a doctor because they bona fide believed such a course to be wrong established that the fact of conscientious objection was no defence to a charge of manslaughter if the neglect to call in medical aid accelerated the death of a child in the care or custody of the accused The Senior case showed conclusively that honest religious belief did not avail the accused It is one thing however, for judges to lay down the law and another thing for juries to convict a father whose obvious affection for his son has placed him in a tragic dilemma The almost superstitious reluctance to allow surgical operations is a survival of which practitioners cannot fail to be aware

AN UNDERGROUND EMERGENCY HOSPITAL FOR AIR-RAID CASUALTIES

BY THE COMMANDANT OF A GENERAL HOSPITAL

WHEN he has completed the organisation and equipment of his hospital for war service the first duty of a commandant is to decide what he will do if it becomes unusable in consequence of explosion, fire interruption of water-supplies or the presence of delayed-action bombs Theoretically such a situation is met by switching casualties to another hospital but in heavy raids this may prove impracticable for many reasons—it may be impossible to communicate immediately with the officer in control of ambulances and roads may be so blocked that alternative routes to other hospitals are not easy to find In any event, by prolonging the journeys of the wounded, and by condemning to inactivity the staff of a hospital when its services are most required, switching is not an ideal solution of the problem I therefore decided to find and equip premises as a sort of reserve or second line to which staff and casualties might rapidly be transferred so that surgical work might continue during a blitz if the hospital was damaged or overcrowded

CHOICE OF A SITE

From every point of view it was desirable that such reserve accommodation should be safer than that of a civilian hospital built to let in light and not to keep out bomb splinters, that it should be as far as possible immune from the nuisances of breaking windows and noise, and that its provision should not involve heavy initial cost or constant expense in overhead charges during quiet periods, or an idle staff permanently in residence for its care Eventually I approached the general manager of a large store This steel and concrete building is within 300 yards of my hospital and has an island site There are nine floors and two of them are underground, the lowest is used for storage and has a subterranean passage for the delivery of merchandise The passage slopes away from the shop and would protect it from serious flooding The next floor—the basement—is used for shopping, and contains a kitchen and a restaurant in which thousands of light meals are served daily, there are numerous lavatories and several lifts, two of which are designed for heavy goods and communicate directly with a covered bay and a loading platform for lorries There are also several wide staircases In another part of England similar premises belonging to the same firm suffered several direct hits in one night from heavy high explosive and were set on fire by oil bombs Great damage was done and the lowest floor was flooded but the basement remained intact

With the consent of the hospital officer I proposed that space in the basement might be set aside for the construction of an efficient operating-theatre, an X-ray room and the installation of sterilising equipment, that arrangements should be made for the rapid clearance of goods from the floor in an emergency, so that h beds could be set up as space became available, and that the kitchen should be used for feeding patients Access to the basement during an air-raid was to be by the covered lorry bay which was well adapted for the unloading of ambulances and by the heavy goods lift which would take stretchers These proposals were approved by the board of the store, who generously decided not only to make no charge for the use of these valuable premises but also to provide similar facilities in other large towns if the arrangement proved useful With the skilful and enthusiastic cooperation of the staff all the structural alterations, plumbing, painting and wiring were completed in three weeks The total cost (exclusive of equipment) was about £1000, though it would have been larger but for the generosity of the firm Later the mayor collected funds privately for the provision of an engine and apparatus to generate an independent electrical supply for light and X-ray work if the city mains were cut

SCOPE AND EQUIPMENT

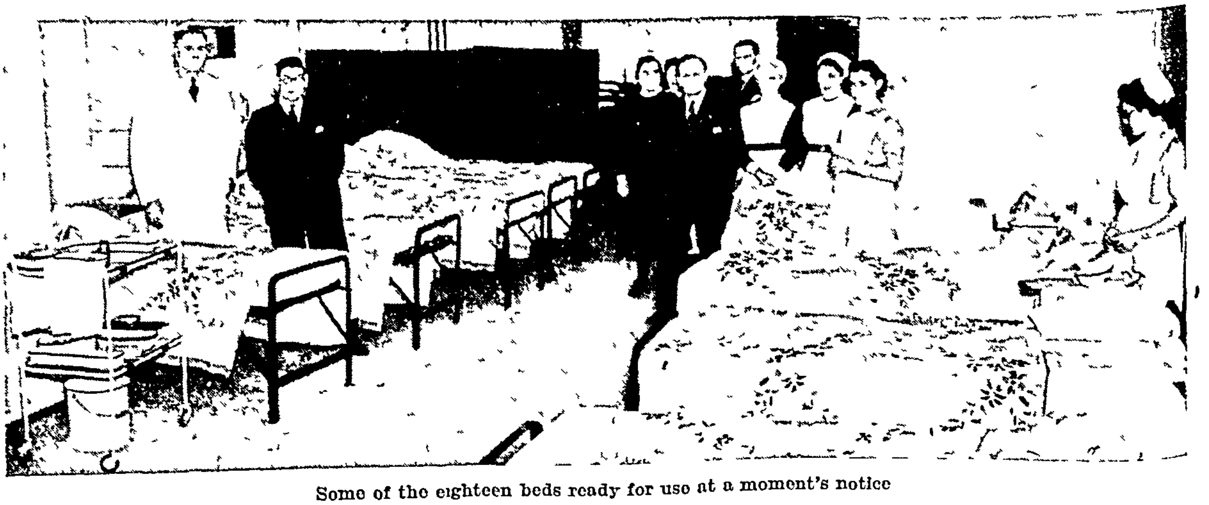
In its final form the nucleus of the underground emergency hospital had a floor space of 2867 sq ft, which could be extended to nearly 8000 sq ft It is separated from a busy shop by interlocking wooden screens The theatre measures 620 sq ft, and is designed for three tables, but it will take four when necessary It is ventilated by forced draught through fine gauze screens To test its efficiency several operations were done in it (including a bone case) before it was used in a raid No sepsis occurred Sterilising is done by electrical heating If the current fails there are gas boilers in the kitchen and as a last resort oil stoves Eighteen beds are kept ready for use On each of these five extra mattresses (with sheets and blankets spread and tied to them with string) are placed to be carried to other bedsteads as they are put up Within an hour, space in the shopping area can be cleared for fifty beds and within two hours a hundred and twenty beds are ready for use The important work of clearing goods is carried out by the store night staff when they receive warning from the hospital, and the speed and efficiency with which it is done is astonishing Standing orders for the use of the basement are now as follows —

1 When 25 casualties have been admitted to the general hospital the store will be warned and will assemble their clearing staff

2 When 50 casualties have been admitted to the general hospital, the basement will be cleared and nursing and registration staff will be transferred to it

3 When 75 casualties have been admitted to the general hospital, ambulances will be sent to the store until 75 cases have been admitted, thereafter the casualties will be divided equally At this stage medical and surgical staffs go to the basement

The bed space is enclosed by interlocking screens and can always be adjusted to the number of patients—th

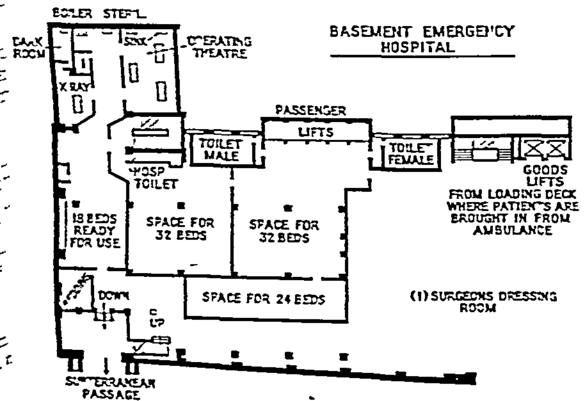


Some of the eighteen beds ready for use at a moment's notice spital expands and contracts like a gigantic concertina r the separation of sexes light ward screens are used refrigerator and equipment for the blood-transfusion vice have been installed, and supplies are changed gularly A bed-pan washer has been connected to e lavatory drain

IN ACTION

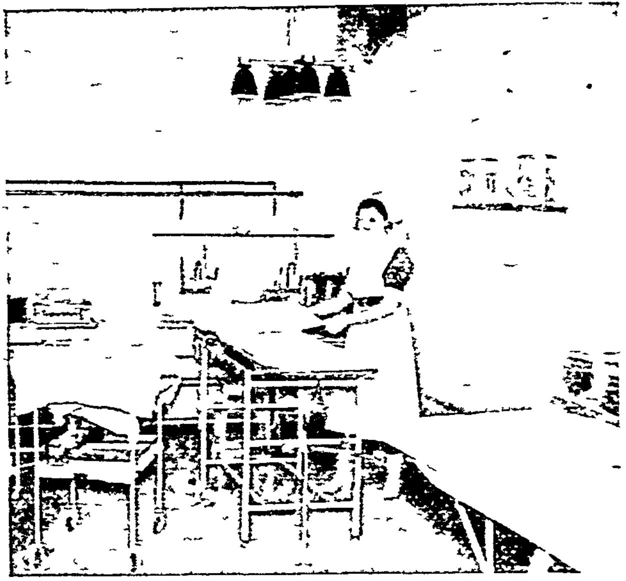
The most severe test of this new model hospital curred early this year One night, when switching on became impossible a large number of casualties were ought to the general hospital One-third of these ere sent on to the store and were admitted within an our Work in the theatre began shortly after midnight 5 minutes after the first admission) and by 9,30 next orning over 70 cases had been dealt with (including veral abdominal wounds) and most of these had been rayed The remainder did not require or were unfit r, urgent surgery The general hospital later became nusable and was evacuated; for a week while repairs ere carried out, the underground hospital remained lly extended and dealt with casualties in the centre of e city Most of the patients admitted to the basement ere evacuated within 24 hours, all of them within days

The X-ray department contains a 4-valve shock-proof nit with tilting couch and screening apparatus It cost 1000 and was provided by the hospitals of the city in the ope that the Ministry of Health would reimburse them or it later It has been suggested that we have been xtravagant and should work with a smaller mobile set do not agree In my hospital we have dealt with over 500 air-raid casualties and experience of them has aught me that efficient radiology is indispensable For fficiency the X-ray room must be easy of access from he theatre and its plant must be capable of continuous se Localisation of foreign bodies and the treatment f fractures is controlled by screening We use very ew films and they are mostly required for dubious bdominal perforations in fat people and for possible enetrations of the skull No light set I am informed ill long survive the amount of screening that we have everal times employed The work is mostly done by he sisters, technicians and students of the radiological epartment, since there are not enough expert radiologists or blitz work Fortunately the technique is simple—ven a physician can learn it in quite a short time



BASEMENT EMERGENCY HOSPITAL

I have read much about the organisation of staffs of ospitals, the writers have been concerned to define xactly the proper functions of a surgeon and a physician n times of stress Most of them seem to miss the ssential point—that the best organisation of any staff that which is best adapted to the capacity of the dividuals that compose it I find it difficult to think f any of my colleagues as a surgeon or a physician ossibly it is the rude air and manners of the provinces hat keep my friends from neatly falling into patterns rthodox and convenient for classification, they main peculiarly, distressingly, and sometimes emphatically individual With material so unruly I have yielded the belief that organisation of staffs should vary from ospital to hospital and that the organisation of a particular hospital should be elastic enough to permit ariation of routine to suit the individuals who are doing



Part of theatre 17 ft below ground

the work at a particular time Matron assures me that the same is true of nurses This digression is not entirely irrelevant to our underground annexe The first essential to the successful working of such a place is a supply of nurses capable of taking the theatre This can only be obtained by rapid and intensive training which involves frequent changes in the staffs of theatres and interferes with their normal slick civilian routine The surgeon who will tolerate this for the larger good is above rubies

I have reached two other conclusions first that the place for a skilled and active surgeon in a blitz is in the theatre There he may well supervise juniors at two or three tables, but he should not leave the theatre except to visit the X-ray room Secondly competent physicians are well able to decide the best order in which cases should go to the theatre and to supervise resuscitation In general they should work with the same surgeons but this should not be a rigid rule

Our aim in a heavy raid is to keep six to eight tables going (three or four in the main hospital and three or four in the underground annexe) as long as casualties require treatment in the theatre We have found that by keeping the surgeons in the theatres, by arranging for X-ray work close by by training larger numbers of nurses for theatre work and by using physicians for sorting and resuscitation we can deal with two or three patients every hour at each table over a long period

CONCLUSION

This experimental underground hospital has shown that it is possible to provide a reserve of theatre accommodation X-ray facilities and beds in large cities at very small capital cost There are no running costs in quiet times since all fire-watching and caretaking are included in that of the main building in which it lies. Daily dusting and cleaning parties only are required In view of the destruction of civilian hospitals our experience may prove to be important, but I want to draw particular attention to another aspect The basement during a blitz has a great appearance of safety, the noise of bombs and barrage is hardly audible and there is no flying glass As a group patients admitted to it recovered more rapidly from shock than did those who went to the parent hospital and the strain on the staff was less and the work was more easily done From an administrative point of view it was convenient to have only one class of case—air-raid casualties—to care for In the parent hospital when rapid evacuation of some wards was necessary there was inevitable confusion and delay in the corridors where the staff tried to sort out by the light of a torch "the perforated gastric done yesterday" from "the abdominal from resuscitation wanted in the theatre" We have been so impressed by the value of the basement that with the approval of the Ministry of Health, another has been prepared with the help of a brewery The firm has gratuitously put at the disposal of the general hospital a large cellar (empty for the sad reason that there is no bottled beer to store in it) 30 ft below ground, with an immensely strong building above it Hot and cold water from artesian wells is laid on and it is centrally heated there is an air-conditioning plant and an automatic electrical pump to raise sewage from a sump A theatre for 4 tables an X-ray room and the other equipment will soon be ready There will be accommodation for seventy beds and there is space for at least another thirty if necessary This cellar will always be available, its main function will be to enable casualties from the densely populated area in which it lies to get effective treatment earlier and to avoid the strain of long ambulance journeys The exact organisation of the staff has not yet been decided This basement differs from the first in being always ready it is not necessary to clear it before it can be used as a hospital In addition to surgical teams and nurses to deal with casualties as occasion requires I would like to try the experiment of staffing it with general practitioners from the neighbourhood (it is about a mile from my hospital) It could then be used as a centre for the ordinary civilian nightwork of the district I would like two general practitioners to be at the basement nightly whose duties would be to go out and visit local sick patients (their own or anybody else's) when called, to bring in and deal with emergencies of civilian practice, to go out with bearers if necessary, to local incidents in air-raids and to help in the work of the basement hospital when air-raid casualties are being treated there The basement would thus serve as a centre for civilian medical service for the local sick, and would help to solve the difficulty of the shortage of doctors in the target areas

WELFARE OF INDUSTRIAL WORKERS

IN May, 1940 the Home Office called an interdepartmental conference to consider the working hours and welfare of women and young persons in factories and raised the question of their welfare under war conditions outside the factories During the last war outside welfare work was organised by the Ministry of Munitions, and it was suggested that this time the Ministry of Labour and National Service should coordinate the various activities which go to make up outside welfare Shortly afterwards as a war measure the administration of the Factories Act was transferred from the Home Office to the Ministry of Labour A new factory and welfare department was established in the ministry and the factory inspectorate was attached to it to continue its work for safety, health and welfare within the factories In addition a new body of welfare officers was appointed to deal outside the factories with such matters as board and lodging transport, day nurseries and the reception of transferred workers The report of the Chief Inspector of Factories for 1940[1] describes how these and other changes have affected factory conditions

CANTEENS AND FOOD

The war of 1914–18 drew increased attention to the human side of industry Preliminary work in this connexion was undertaken by the factory inspectorate and was afterwards developed on the advice of the Health of Munition Workers Committee In the interval between the two wars factory conditions have improved under the influence of voluntary societies and also under the stimulus of legal orders For example the order requiring mess-rooms in certain trades has resulted in the establishment of canteens in some of the larger factories and welfare orders have brought about improvements in first-aid washing accommodation and seating arrangements In many cases though still a minority the standard of these amenities was better than that legally required and the Chief Inspector's report pays a tribute to those employers who have thus gone farther than the law requires By early in 1940 canteens had been established in 61% of those works engaged in munition-making which employed over 500 people In parts of the south of England the figure as high as 90%, but the percentage fell as one north where the canteen habit, for various reasons, never been popular with the workers To in canteen facilities still further the Factories Ca Order 1940 (No 1993) was made, under which occupier of any factory employing more than 250 and doing work on behalf of the Crown must provi canteen where hot meals can be bought This wa first legal order requiring canteens in factories, althou many previous orders had stipulated that mess roo should be provided A mess-room is a place where mea brought in can be eaten and there is a supply of ho water and arrangements for heating food brought fro home by the worker In a canteen, on the other han meals are sold It was clearly necessary to establi canteens in factories because rationing made it difficu to obtain portable food for a midday meal, and becau (as Napoleon was aware) a man will work better if h is well fed Other factors which called for increased feeding facilities were the extension of night work and the shift systems, the employment of A R P and fire-watching staff, and the destruction by enemy action of the workers' houses and many public restaurants Difficulties arose because materials were controlled and limited, but the Factory Department has had sympathetic help from the departments controlling supplies and no further difficulty is to be anticipated in the erection and equipment of essential canteens Efforts to provide hot meals for workers in the smaller factories have not been so successful The idea of providing joint canteens for a number of small factories met with little response from either the employers or the workers, and the possibility is now being considered of using the community feeding arrangements of the Ministry of Food and the local authorities It is hoped that in many cases food will be sent from the communal centres to the mess rooms of the smaller factories The feeding of dock workers became a pressing problem and the Factory Department was given the job of solving the administrative details The minister issued an order (No 222 of 1941) under which the dock authorities can be required to provide canteens and permanent ones are now bein built to supplement the existing feeding arrangements In the meantime excellent work has been done on th docks by the mobile canteens of the Women's Voluntar Service and other voluntary bodies but the repo points out that the voluntary organisations deal on with emergencies and are not to be used as an exc for not providing permanent canteen facilities

BUILDING SITES

It had never been the custom in peace time to provid much in the way of amenities for workers on building and engineering construction sites, partly because the contractors would normally have ample time to consid their plans and partly because the British navvy wa thought to be able to look after himself But the gr extension of the Government building of new munit factories aerodromes and camps led to difficulties o labour, housing, feeding sanitary accommodation a transport The Ministry had to give earnest conside tion to the conditions at the building camps, and th factory inspectors were given the duty of improvi welfare conditions At the same time the mini announced his intention of making an order und which better organisation on the sites could be leg required The order (No 66) was issued in Janua 1941 and at about the same time a pamphlet[2] contain detailed recommendations to contractors was also pu lished In the early days of the war conditions we bad on many of these sites and on a few they we deplorable mainly because the work had to be carri out at great speed but also because there was usually no-one on the contractors staff whose duty it was to look after the workers Contractors have been ur to appoint welfare officers and where this has been do their services have been of great value The lat reports show that conditions on building sites are rapidly improving

MEDICAL, NURSING AND WELFARE SUPERVISION

Previous reference has been made in these columns[3] the order issued in July, 1940, by the Minister of bour empowering the Chief Inspector of Factories to for the appointment of doctors, nurses and welfare pervisors in any factory doing work on behalf of the own. Dr Bridge in his short report refers to the anifold difficulties of developing a comprehensive dical service in factories—for instance, the limited mber of doctors available for and interested in the ork. and the doubts which medical supervision of the orker raises in the minds of the workers, employers d the doctors themselves Some have doubts whether man should be asked to submit to medical examination a doctor other than one of his own choice, others onder whether any need exists for a medical service yond that already provided under National Health nsurance Nevertheless progress has been made and n increasing number of whole- or part-time medical ficers continue to be appointed to factories It has ways been apparent, Dr Bridge says, that unless the odwill and coöperation of both employers and em-loyees is forthcoming the work of a medical officer, hole-time or part-time, is unlikely to be of real value Much still remains to be done, and it may be that in a ew cases use will have to be made of the compulsory owers provided by the order Fully trained nurses re entering industry in increasing numbers and special ourses on the industrial aspects of nursing are being eld by the Royal College of Nursing by arrangement ith the ministry, which in some cases gives financial ssistance to nurses selected for training

PRAISE FROM THE ARGENTINE

THE Argentine Pro-Allies Commission has been distributing as a pamphlet the presidential address given o the Argentine Association of English Culture by Prof Mariano Castex,[4] head of the department of clinical medicine in Buenos Aires University, who received an honorary M D Oxfd last year Professor Castex took as his theme the debt of science and humanity to British medicine, and he gives a concise but perspicacious urvey of the outstanding figures from Linacre to our living Nobel prizemen It is inspiring to read this stimate of our national achievement by a representative of the great Spanish tradition writing from Buenos Aires, which is now, as Cajal points out, the real centre of that radition Professor Castex sees in the English spirit a reative originality based on a will to knowledge, and notes the singular flavour of modernity in Sydenham's work He links the name of Harvey, in whom "every rue doctor must rejoice," with those of Sir James Mackenzie and Sir Thomas Lewis, he connects the urrent interest in biophysics at Buenos Aires with the pioneer work of Stephen Hales He attributes the rise f preventive medicine to eighteenth-century England, and sees in Jenner the triumphant vindicator of English methods and perseverance He points out Britain's re-eminent contributions in the last century to physi-logy, cardiology, tropical medicine and surgery astex praises the men as well as their work, quoting ith warm approval Lister's precept "Put yourself in he patient's place" Coming to our own day, he con-ludes that the twentieth century exceeds its pre-ecessors in brilliance "British scientists are endowed ith a spirit of asceticism and high moral purpose, so hat their outstanding achievements in practice and esearch have been made in an atmosphere of idealism, bnegation and humanity" He concludes that our uccessful union of tradition and progress makes British edicine worthy of the virtues which he attributes to us as nation, a list too shy-making to repeat in plain English

WINCHESTER AND DISTRICT MILITARY MEDICAL SOCIETY —A meeting of this society will be held at the Royal Victoria Hospital, Netley, on Monday, Oct 27, at 3 P M, when urgeon Lieut Commander John Bunyan, L D S will give an address on the treatment of burns and wounds by the envelope method

In England Now

A Running Commentary by Peripatetic Correspondents

As I follow my molluscan life, mow the lawn or sit in surgeries I often think what tales they'll have to tell those lads from whom our thoughts are rarely absent—*tales of Tobruk, epics from Crete and the Epirus sagas* of the skies Then I'm not so sure I remember going several times to an Armistice Day tea in an English village given by the local lady, Lady Pouncey It was an excellent meal and the Hodges threw out from time to time cheerful remarks of *chaff or crops or cricket—all* current affairs Then Lady Pouncey would sail along with cakes or sandwiches "Talking of the good old times, boys? That's right Those were the days" She was right, they were for her Her husband had been made a knight for doing something to munitions and she had had ample scope for her bossy benevolence As she passed along with her cakes and cheery remarks an awful silence fell on those wooden benches Those memories had been packed up and she was tearing the brown paper off the parcel "Dear Liz, don't let the children forget me We're orlrite so far Kiss baby We move up tomorrow" The captions were simple enough, but a wise censor had suppressed the vivid and squalid film Yes great tales will be told but probably second-hand by some house-loving Homer, who'll catch the glamour but not the lice, feel the thrill without the fear, supply sustained suspense in many chapters ignorant of its raw material, the twisting of souls the carking awl of tedium, the crude smell of butchered men They'll probably give the book as a school prize—"An absolute classic, my dear boy"

* * *

When our phlebotomy team is invited to visit the manor house we are nearly always assured of willing subjects Sometimes we are billed as being 'at home" to volunteers "Bleeding 7 30–10 P M Refreshments in the gun-room afterwards" However, in a small rural community one has to be sure that those who attend are genuine volunteers It may be very difficult to refuse a pressing invitation from the vicar's wife to take part in the Upper Woople and Lesser Slugsbury Combined Blood-transfusion Drive, and the number of press-ganged victims may be quite noticeable A brief analysis of the facies of the local organiser will usually give the clue as to what to expect Once we were received in a lovely old house situated on top of a hill overlooking a valley Our hostess was elderly and too frail for her blood to be of service to us She had therefore begged that she might entertain the local donors and help the doctors and nurses In the drawing-room only one couch was available for our use early Victorian in design Spartan in its discomfort and very low on the ground, phlebotomy was slow going and backbreaking The dining-room was set aside for coffee and home-made oatcakes As we knelt down to insert the needle a Rockingham unicorn grinned down on us from a tallboy and as the list progressed and the twilight of an early spring evening advanced candles were lit and held near us by the frail old lady As the evening wore on the unicorn's gaze seemed to become less fixed and he, like us betrayed ingravescent somnolence The night was pitchblack and stormy as we carried away our crates of blood to the car by the aid of our hostess's hurricane lamp Within four days a neighbouring town suffered a severe raid, and we were glad the blood was there

Bleeding on the lawn is a recent innovation with us We discussed the pros and cons around the tea-table and decided that the dangers of chill, sunstroke and spore-bearing organisms were outweighed by the bactericidal advantages of sunlight, and the heartening effects of fresh air and the song of the skylark. The skylark did in fact prove most helpful and when he went off duty a small brown owl elected to take his place and see the list through An unforeseen complication was a hæmatoma at the site of venepuncture, due to an aggressive horsefly who alighted maliciously on the dorsum of the hand steadying the needle But there is undoubtedly much to be said for bleeding out of doors, and we have yet to see a volunteer so bled turn faint.

The value of music in phlebotomy was later investigated at a barracks, as the logical development of the important part played by the skylark Half the ward was set aside for bleeding operations, the rest being occupied by Service sick and convalescents The Forces programme was on and we were able to compare the relative influence of "Salut d'Amour" and "The Washington Post" The rate of flow was distinctly *rubato* with the former, but it came along nicely with the latter, while the "Boston Two-Step" caused the bottles to fill at an almost alarming rate The ideal tempo for a blut-motif is *allegro ma non troppo*, but the temperamentally difficult vein of the stout middle-aged blonde donor reacts well to *allegretto grazioso* The thin, small, fussy and good-natured elderly housewife is quite at home with *vivace* and she will fill her bottle faster than any But on no account should the hypertensive general be bled to *allegro con fuoco* while anything in the nature of a *galop de concert* should be shunned, for this gentleman's time is strictly *lento*, or at the most *allegretto con poco rallentando* One advantage of music-while-you-bleed is that it becomes wellnigh impossible for the donor to hear his blood pouring into the bottle, a sound usually not well tolerated It saves the doctor from having to keep up a continuous conversation and from the monotony of reproducing parrot-wise, in answer to questions, certain elementary principles of immunology not normally comprehendable by the bleeding public (this is not a disrespectful remark)

Our donors at the barracks had all given up their off-duty time to make their donation Moreover, practically all the convalescents, who had been nonchalantly eating boiled eggs during the proceedings (pre-June, 1941, you will note), offered themselves as volunteers On several of our country excursions we have been assisted by rural district ambulance teams who have supported their stretchers on kitchen or other (on one occasion they were Adam) chairs on the lawn The able officer-in-charge, the well-waxed discipline of whose moustache was reflected in the alertness and efficiency of his team, sent his pretty stretcher-bearers to help us Mary, a lithe, blonde milkmaid from a neighbouring farm, brought her three-legged stool with her and squatted down beside the donor holding the bottle in her lap Early on in the transfusion campaign we had established a bond of sympathy with the dairyman, the provision of aluminium crates for transport being an important link The advent of Mary and her little stool seemed to complete the analogy between the milk and the blood businesses, and we decided to anticipate trouble and institute a Blood Marketing Board for the fairer distribution of plasma in the various hospitals in the area At one of our out-of-door parties we noticed a curious form of local gossip On this occasion the blood, after collection, had been placed in the shade under a beech hedge When the number of completed bottles had exceeded twenty we noticed the late comers and some who "didn't think they would this time but would like to be tested" filing past the bottles on all fours "Mrs S didn't give much, did she? I thought she hadn't it in her" "Oh and fancy, here's Mrs B's, her with all them rheumatics and who's no sooner out of one quinsey than she's into another, I'd never 'ave thought they'd have taken off her They'll be taking Ted's next" "I wouldn't like to have some of this blood put into me"

* * *

The late Bishop Welldon, when Metropolitan of India, knew a man whose three professions conferred on him the title of "the reverend doctor colonel" Moreover, it is said that the matrons of some hospitals are today preferring to call themselves "lady superintendents" And who has forgotten Mr Jack Warner's "bunger-up of rat-holes"? The first and the last tell what a man's job is, the second is an example of the petty pride which makes everyone love a title, be he peer, churchwarden or acting unpaid lance-corporal Both in the primitive tribal society of darkest Africa and in the more backward society of blacked-out Europe men seek for a label that they may stand apart from their fellows and say, "Thank God I am not as others" And a very good thing it is How drab would be life without a Deputy Chairman of Ways and Means, how dull without a Master of Foxhounds

We are taught in medicine to treat the patient, not the disease, and our teachers beg us to have always before us the human relationship between patient and relationship of privilege shared, perhaps, only by men To the patient his doctor is his own au whom he places his trust In this relationship the no officialdom The patient is an individual, so is doctor The average man, particularly of the class, has a healthy distrust of anyone "authorities" He expects his doctor to be *his* and different from the man who reads the meter, landlord's rent collector, or the clerk at the exchange, all of whom are officials Now wherever state takes a hand it brings its own jargon In medic it brings health officers, tuberculosis officers, medi officers grades I and II, group officers, sector offic officers of all sorts If only because of this unimagina terminology, gone is that relationship between patient doctor, it is replaced by that between citizen and offic

To be justified, a title must be well chosen and suit affixed Why cannot the state and municipal authori have plain doctors physicians and surgeons? The "doctor" is honourable enough, having the author learning and the sanction of history, though presum not the approval of the Ministry of Health or the To Hall "Physician" and "surgeon" mean what th say It is no distinction for a house man to be called medical officer, even if he is grade A, like an unobtainab egg Anyway, he will soon be in the only place where the term is justified—with the forces

* * *

The sartorial habits of our students in their new rural surroundings are indeed striking Flannel trousers and sports jackets have ascended the fashion scale at a phenomenal speed In the prewar days (already being referred to affectionately as the "old days") these articles, while worn extensively in the preclinical period, were considered démodé in the clinical period, except possibly on Saturday mornings Now they are the acme of fashion, while some of the outfits worn have to be seen to be believed Shorts are extremely popular, sandals are considered rather smart, slippers are often worn if day should be fine shirts are as varied in hue as th dragon-flies which flourish in our neighbourhood whil ties have almost disappeared The return of the blaz would warm the hearts of all good Edwardians C duroy trousers spring up like mushrooms overnight, I am dreading the atmosphere of my laboratory in th coming winter when, with every door and window seal in an attempt to maintain a reasonable temperatu the room is filled with a mob of corduroy embellished occupants fresh from a damp journey I only trust th "stinks" may not become the medical students', a well as the schoolboys', synonym for my subject H of course, do not exist—a reform which has my compl support Since I was evacuated I have never sported not even on my weekly visits to town What the effe of clothes rationing on all this will be remains to be se

* * *

To me it is always sad to read, as I did not long a of a great circus closing down Difficulties in black out the Big Top and in getting animal feeding st were blamed Musing disconsolately upon the f reaching effects of war I was a little comforted to ob a notice hung in the front hall of my *home* which as follows

A CIRCUS WILL BE HELD AT 3 A M ON WEDNESDAY ON T PEICE OF GROUND IN FRONT OF THE SCULERY WINDO ADMISSION CHILDREN A PENNY, GROWN UPS TWOPEN PERSONS UNDER 5 FREE THE MAJORITY OF THE MONEY WI BE SENT TO THE HOSPITAL ANYONE CAN COME

There were six performers, four human and th others nearly so, if I may say as much without giv offence to the patient pony and elderly neuter go who had a good deal to put up with and cooperated the most friendly fashion There were seven turn all, and, good as the acrobats and trapeze artists were, I personally liked best the pogo horse whose brown contrasted strikingly with his greenish tinted b curiously reminiscent of a groundsheet I also en the undressing tramp and the clowns and their tr with animals As to what is to happen to the minor of the money contributed by a large and enthusi audience I have not yet dared to inquire The question has given trouble enough in the past few

Parliament

Civil Defence Progress

the House of Lords on Oct 15 the Bishop of CHESTER asked the Government what steps had been n against the coming winter to improve our air-raid ters, to give immediate help to the homeless and to vide accommodation for the aged and infirm in ibed areas Lord SNELL, who replied, agreed that as the responsibility of the Government to meet the ple's heroism with foresight and preparation and it ild be foolish to say that everything was satisfactory, it was some comfort that about 20 million people ld now be sheltered The aim of the Government to provide shelters at or near their homes for all h an income of less than about £350 a year Some ,000 Morrison table shelters had been allocated in nerable areas and 20,000 additional tables were being de each week Deep shelters were being developed ough the London tube system, and last June a nphlet was issued laying down standards of sanitation ating, lighting, ventilation, bunking and cleansing ntrol and supervision based on the recommenda- ns of Lord Horder's committee, and on London's actical experience of last winter Further recommen- tions about amenities in shelters by the Horder com- ttee had been dealt with by a new Defence Regulation ving powers to the regional commissioner to undertake ch matters as undesirable people in shelters and rminous bedding In England and Wales, Lord Snell ntinued, 11,500 first-line rest centres had been estab- hed with accommodation for over a million people ere was accommodation for a further million in second- e centres By July of this year 2167 shelters in London d been supplied with canteens, at which 100,000 people re served with food Mobile canteens were used erever possible The Ministry of Food, through the cal authorities, had emergency stocks of food in the fferent localities The Government realised the need r tackling the question of providing safety for the aged d infirm They present a very human problem, but tural reluctance to go and live among strange people ten conflicted with the needs of the nation

Service Dependants

In the debate on Oct 16 on the new scheme for allow- ces to service men's dependants members made it ar that what the Government described as a White per was more like an ungenerous tangle of red tape, d not even Sir WALTER WOMERSLEY's sympathetic position could reconcile the House to it Indeed it is felt that the Service departments had left him with a ge and unhealthy baby to hold, suffering—Mr LLACHER suggested—from malnutrition The most portant change in the new system is that a minimum ndard for *maintenance*, after providing for rent and her commitments, has now been fixed For an adult e figure is 16*s*, and two children under school-leaving e count as one unit The maximum grant that can made has been raised from £2 to £3 Where there was sickness in a Service man's family allowance up to £10 will be made, and if this does not ver the position Sir Walter said that he would ask authority to give more Amounts of £2 and below ll not be taken into account Where there is a death the family a payment of £7 10*s* will be made The esent cost of war service grants is about £5,500,000 per num, and it is estimated that the new concessions will st another £6,000,000, while extra publicity will probably sult in extra claims which might be expected to amount some £2,000,000, making a total of £13,500,000 The Treasury had vetoed the possibility of a flat rate grounds of expense, but the House was riled that se concessions should still be based on what Mr OBBII described as the mean contemptuous means ts, and Dr HADEN GUEST voiced a general fear that practice the scheme was likely to prove neither efficient r economical The House agreed that adequate pay d allowances would spare both personal feelings and the bour and paper involved in sifting innumerable claims

Supplies of liquid milk are made available for operational A F crews when recommended by station medical officers r ARCHIBALD SINCLAIR replying to Sir ROBERT GOWER.)

QUESTION TIME

Nurses' Salaries

Replying to Miss M LLOYD GEORGE, the MINISTER OF HEALTH stated that he had appointed Lord Rushcliffe as chairman of the committee which he had formed to draw up, as soon as possible, agreed scales of salaries and emoluments for state-registered nurses employed in England and Wales in hospitals and in the public health services, including the service of district nursing, and for student nurses in hospitals approved as training schools by the General Nursing Council The committee will consist of two panels, one representing employers and the other representing employees, of equal numbers Mr Brown said he hoped to announce the names of the committee in about a fortnight Miss I WARD Will the committee have powers to make recommendations with regard to nurses employed in industry —Mr BROWN No It would not, in my view, be appropriate to refer to this committee the salaries of this class of nurse

Mr T JOHNSTON also announced that he is setting up a similar committee for Scotland under the chairmanship of Lord Craigmyle

Alien Doctors

Sir HENRY MORRIS JONES asked the Minister how many friendly alien doctors were now employed in their own work in our war effort, giving the different spheres of employment, whether any were in our services, whether any further avenue of war service was being offered to them, and how many alien doctors of all nationalities, except the United States of America, were still available —Mr BROWN replied The number of alien doctors registered under the Medical Register (Temporary Registration) Orders, 1941, by virtue of employment in approved services is 470, apart from American doctors who have been dealt with under the order of 1940 Of the total of 470, 385 are employed in hospitals, 33 in public health appointments, and 52 as ships' surgeons or in other miscellaneous posts In addition 24 have received commissions in our Services, apart from those serving in Allied Forces The order made on Sept 23 last provides an avenue of service in general practice by enabling alien doctors to be registered by virtue of employment as assistants to doctors already on the permanent Medical Register The number of doctors still available is approximately 500, including those who have only recently become eligible for registration under the amended Defence Regulation 32 B

Treatment for Soldiers' Families

In answer to Major HADEN GUEST, Captain H D R MARGESSON said that the extension to the families of soldiers enlisted since the war of the facilities for medical and dental treatment at present enjoyed by the families of pre war regular soldiers or reservists now serving would involve an enormous increase in the numbers of Army medical and dental officers which could only be effected at the expense of the civil medical services Moreover, the families of pre war regular soldiers are not eligible for medical attendance in their homes unless they live within a mile of certain fixed points, and, if the concession were extended to the families of war time soldiers, its value would therefore vary according to the family's domicile

Grass as a Source of Protein

Dr SUMMERSKILL asked the parliamentary secretary to the Ministry of Food whether he proposed to use grass as a source of protein —Major LLOYD GEORGE replied Research work on the production of edible protein from young grass is proceeding There are however considerable technical difficulties to be overcome before any large scale production can be contemplated A sort of greyish material looking like cheese had been discovered, but only on an experimental scale

War-time Nurseries

In reply to a question Mr BROWN said that 156 maternity and child welfare authorities have submitted plans for war-time nurseries, 221 nurseries have now been approved. Of these 163 were in operation at the end of September It is not possible to say the exact number of children in attendance at these nurseries but the nurseries approved provide places for about 4250 children

Hygiene in Air-raid Shelters

In answer to a question Mr BROWN said substantial improvements have been made in dormitory air raid shelters throughout the country Progress is continuing but shortage of materials and labour has unfortunately prevented complete provision to the standards I have laid down Canteens are available in over 2000 shelters in the London region Schemes have been agreed with 90 local authorities in provincial vulnerable areas and many canteens have already been provided In the London region 257 medical aid posts have been set up, and over 100 in the provinces Plans have been made for setting up further posts should the dormitory shelter population increase

Increase of Tuberculosis

Mr F MESSER asked the Minister of Health what had been the percentage increase in pulmonary tuberculosis during the war, in what age groups the increase was most marked, and if it was proposed to take any special steps to deal with this problem —Mr BROWN replied On the basis of provisional mortality figures for the years 1939 and 1940, the rate in England and Wales for the population as a was 9 7% higher than in 1939, the highest rate among women between the ages of 15 and 25 In the quarter of 1941 there was, however, a reduction of 7 the population as a whole, and of 4% for women the ages of 15 and 25 With the cooperation of the Research Council I have arranged for an expert inve into the causes of increase Everything possible is being to maintain the tuberculosis service

Milk Scheme in Scotland

The total number of beneficiaries under the National Scheme for Scotland on Sept 27 was 358,200 The annual cost of the scheme in Scotland is estimat £1,540,000, including an allowance for admini expenses (Major LLOYD GEORGE replying to M BOOTHBY)

Letters to the Editor

ANÆSTHETIST AND SURGEON

SIR,—The position of the anæsthetist in the scheme of things surgical has altered sensibly during the past few years He is no longer to be regarded as a pure technician whose work begins and ends with the administration of the anæsthetic during the operation Enthusiasts like Hewitt, Shipway, Boyle and Hewer gradually raised the standard of anæsthesia, until, with the introduction of a high-standard diploma in anæsthetics, it finally achieved the status of a specialty The anæsthetist of today should actively embrace in his field of work problems of pre- and post-anæsthetic care that are complementary to those of the surgeon The latter should feel, and it must be granted that many surgeons want to feel, that in the anæsthetist he has a pillar of support, and a colleague whose opinion he will seek and value

The nature of the operation may be decided by the report of the anæsthetist on the patient's pre-anæsthetic condition, while after the operation he is ready with his experience in the administration and handling of gases, to help and advise with such things as oxygen therapy In the theatre, without doubt, the surgeon must be the captain But the anæsthetist is his chief engineer, supreme in his own sphere, whose reports are vital if the ship is to be brought safely to port During the operation, the anæsthetist must make himself responsible, not only for the administration of the anæsthetic and the observation of the patient, but also for the administration of resuscitative measures like transfusion This has been recently stressed by Jarman and Evans in a discussion of factors which make for safety in the operative treatment of carcinoma of the rectum (*Proc R Soc Med* 1941, 34, 711) They insist on the control of the blood-pressure being in the hands of the anæsthetist

If however the anæsthetist is to take his place in the surgical team, he must be a clinician as well as an applied physiologist Hospital authorities should realise the necessity for the anæsthetist having sufficient time away from the theatre so that, like his surgical colleagues, he can visit his patients both before and after the operation All too often, anæsthetists, especially those in full-time service, spend all their working time in the operating theatre, a state of affairs due largely to the lack of junior assistants Were more junior posts created, the harassed senior could spend more time in the wards—to the advantage of the patient, himself, and his specialty—and new recruits to a most important field of work would be given a chance to gain experience

Dartford, Kent W W MUSHIN

MEDICAL ASPECTS OF BOXING

SIR,—I was very interested in your review of Dr Jokl's book and the correspondence ensuing from his deductions As a boxer with experience of over 52 contests, and the good fortune to win many titles in the ring, mostly by knock-outs, I would like to express my own view My contact with boxers, both amateur and professional, has extended over 20 years, and I must honestly say that I have never come across the direct injuries or sequelæ described by Dr Jokl I realise, of course, that Dr Jokl has made a wide-world study of this subject, and do not doubt that injuries such as he has described occur if the contestants are unevenly matched, untr neglect to procure a medical examination before a test, and above all are not under competent instru or medical supervision The only direct injuries I h encountered have been broken nasal septums, abra of the skin and cauliflower ears, while black eyes lo teeth and laceration of the eyebrows were very commo Sprains, especially of the ligaments of the hands, a numerous but I have never seen a Bennett's fractu in either a professional or an amateur boxer Fouls such as kidney punches, wrestling hitting below the belt, and so on, are well controlled by competent refere and therefore do not cause much injury Concussion delivered by the closed glove or by the occiput hitting the ring is only momentary and I have never seen it leave any after effects, except in a few cases a brief headache I have been knocked out myself and knocked down on many occasions with none of the results or sequelæ described by Dr Jokl Blows on the abdomen above the belt, or over the heart, do cause a momentary los of consciousness, but the effects in a properly traine individual are negligible I have never seen any accrue from body blows as approved by a referee, althou I agree that loss of consciousness is due to inhibition the heart for a few seconds

The sequelæ that Dr Jokl mentions may indeed o when the fight has not been under proper contr medical supervision, and in those boxers who ag medical advice, allow themselves to be used as chop blocks Punch-drunkenness is a very rare condi found in second-rate sparring partners Some of th have a history of syphilitic disease which accentua the symptoms I have never seen punch drunken in first-class amateur or professional boxers In cranial hæmorrhage due to direct injury by the g is also very rare, and I have never seen any nerv lesion such as peripheral or central paralysis, ca by a punch Injuries to the superficial tissues of t eye can stop a boxing career, but that is all, they h no permanent effect A deflected nasal septum wh has not been treated may in later life lead to sinu in tion, while injuries to the ligaments of the hand c cause arthritic changes Boxers who have had a l boxing career and have not consulted a doctor develop retinal hæmorrhage or even a detached r but these cases again are exceptional Pulmo tuberculosis is another sequel of boxing and one I w like to stress I have seen many boxers in their p and after the close of their careers become victi galloping pulmonary tuberculosis If only they been screened in the early stages (or indeed in some c in the later stages) much could have been done for th I have noticed in some cases that the tubercul infection was latent until exercise, the dust of the with its attendant grit, and perhaps the trauma of gloves on the chest, have sent them into gallop tuberculosis For this reason I have always ad boxers with a history of T B in their family or sympt of bronchial trouble to be X rayed before participat in this sport, and have advocated training and spa in the open away from a dusty gym

From my experience and from Dr Jokl's finding think that given proper medical supervision, prope matched opponents, and control under competent refe and instructors, boxing would lose any stigma whic attached to it and much of the æsthetic antagonism h many people undoubtedly have against boxing d be mitigated I cannot agree with Dr Jokl that a game that should be barred from the physical ation of the young men of the nation and armed s Fighting is man s natural heritage and under rules of true sportsmanship the noble art instead of ging out the bad qualities brings out the good, teaching us to give and take to stand on our own feet to play game and above all to appreciate the ups and downs ur fellow men Dr Jokl has given us much food for ught but he has painted only one side of the picture ncy that if he had given full weight to the safeguards ch now exist (and which can easily be intensified in Services if necessary) his strictures on the noble art ıld have been much less severe I have fought some is countrymen—good boxers they were too—and I feel e that those of them who are medical men in South ıca will agree with me that

Boxing is a manly game
'Tis Britain s recreation,
By boxing we shall raise our fame
Above every other nation

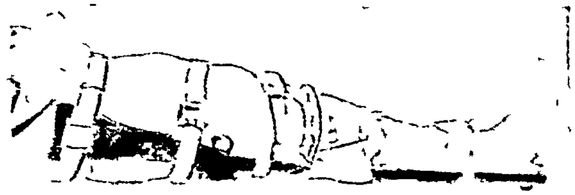
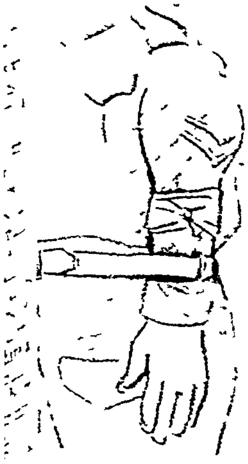
HOME GUARD PROBLEMS

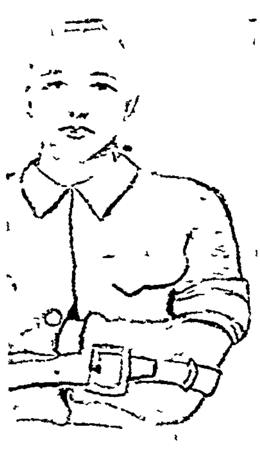
ɔIR —To what extent medical equipment should be ued to the Home Guard is a problem which affects al areas more than urban ones, for the reasons already en by Mr Lawrence Abel In a rural area, such as medical equipment must be dispersed But should ask either the War Office or the Canadian Red Cross supply our needs ? The E M S is now an established ttress of our social structure It already shares with litary hospitals the responsibility for giving institunal treatment to Home Guard as well as Service ıalties It has undertaken the task of decentralising spital facilities and it could therefore correlate the rochial problem of the Home Guard casualty scheme ch its own Costing the Government sixteen million unds a year the E M S might reasonably be made ponsible for the expenditure of the other half million unds which Mr Lawrence Abel assures us would be ent once only—to equip 50,000 posts Lastly, the M S has a personnel of 1700 full-time doctors, colleagues whom harassed battalion M O s should find more approachable than the nebulous authors of incoherent "A C I s"



llinting of fractured femur using sound leg, rifle two belts two ield dressings two anklets handkerchief and boot laces tied ogether

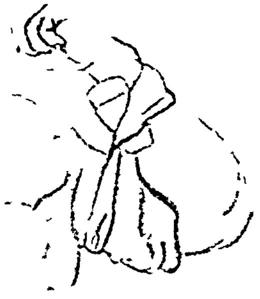


Fracture at elbow



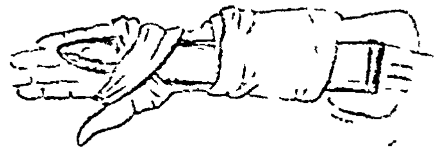
Compound fracture of humerus

Most correspondents have been concerned with the inadequacies of medical equipment As the M O of a well-dressed city battalion may I stress with diagrams the usefulness of the equipment which every volunteer carries on his person ? His leather belt and anklets squeak when he is paratrapping but they make excellent first-aid equipment when he is a casualty , as also do his rifle, bayonet-scabbard bootlaces, haversack-straps and pocket handkerchief If necessary, this equipment can be duplicated by the "pal" attending the casualty In addition, Mr Lawrence Abel says that each man should carry an 18 ft by 3 in roller bandage, and a thick piece of cord attached to his mackintosh-cape ground-sheet As the official issue of the latter is one to four volunteers, and the actual issue considerably less than that, the second part of his suggestion is not universally applicable Moreover when it is remembered that the casualty and his pal between them carry 16 ft of bandage attached to their first-field dressings is the additional roller bandage necessary ? My own fancy is for a triangular bandage I have advised every volunteer to buy one and to carry it in a pocket of his haversack—and nowhere else The most urgent use for it would be as a comparatively harmless tourniquet



Hæmorrhage from forearm controlled by rolled sleeve and field dressing tied as figure of eight

My own special problem has been the difficulties of instruction Like the War Office itself platoon commanders are not unnaturally obsessed with the importance of guns, and combatants are not encouraged to learn the implications of my motto *festina lenter* and the gentle art of splinting fractures and minimising shock In a city supplied with full-time A R P first-aid parties, it is not easy to convince Home Guards that thorough knowledge of a little first-aid is the duty of every fighting man A recent field exercise has indicated that demonstration of first-aid to a company en masse is a waste of time In order to learn the "Woodford and Wanstead" method of blanketing for example, men must themselves handle the stretcher and fold the blankets They must practise it not once but several times This can be done only by individual instruction and therefore cannot be attempted by the battalion M O Each company commander has therefore appointed a medical orderly whose combatant duties are nominal, and who has since been trained to teach the elementary first-aid and stretcher drill required The medical orderlies have been given the rank of corporal and are responsible to the battalion M O , with whom they constitute a committee which meets once a fortnight In each company a rota for instruction has been arranged so that each section (12 to 15 men) will in turn be taught by the company medical orderly on the weekly "platoon night" When practised in their "stretcher-bearer" duties, men are inspected in squads of four by the M O , who tests their knowledge of the following syllabus —



Splinting of fractured forearm using bayonet scabbard, handkerchief and field dressing

The control of bleeding and the dangers of a tourniquet The handling of fractures, and the use which can be made of first field dressings and personal equipment Carrying blankets in the closed stretcher Blanketing of casualties and the importance of warmth Stretcher drill and the importance of gentleness

The proficient volunteers are given "S.B" brassards [illegible] company commanders of materials and labour has unfortunately prevented complete provision to the standards I have laid down   Canteens are available in over 2000 shelters in the London region   Schemes have been agreed with 90 local authorities in provincial vulnerable areas and many canteens have already been provided   In the London region 257 medical aid posts have been set up, and over 100 in the provinces   Plans have been made for setting up further posts should the dormitory shelter population increase

Increase of Tuberculosis

Mr F Messer asked the Minister of Health what had been the percentage increase in pulmonary tuberculosis during the war, in what age groups the increase was most marked, and if it was proposed to take any special steps to deal with this problem —Mr Brown replied   On the basis of provisional mortality figures for the years 1939 and 1940, the rate in England and Wales for the population as a was 9 7% higher than in 1939, the highest rate among women between the ages of 15 and 25   In quarter of 1941 there was, however, a reduction of the population as a whole, and of 4% for women the ages of 15 and 25   With the cooperation of the Research Council I have arranged for an expert inve into the causes of increase   Everything possible is being to maintain the tuberculosis service

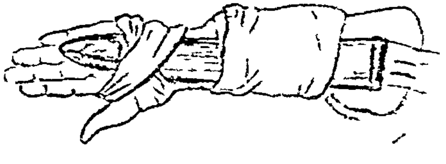
My own special problem has been the difficulties of instruction Like the War Office itself, platoon commanders are not unnaturally obsessed with the importance of guns, and combatants are not encouraged to learn the implications of my motto *festina lente*, and the gentle art of splinting fractures and minimising shock In a city supplied with full-time A R P first-aid parties, it is not easy to convince Home Guards that thorough knowledge of a little first-aid is the duty of every fighting man A recent field exercise has indicated that demonstration of first-aid to a company en masse is a waste of time In order to learn the "Woodford and Wanstead" method of blanketing, for example, men must themselves handle the stretcher and fold the blankets They must practise it not once but several times This can be done only by individual instruction and therefore cannot be attempted by the battalion M O Each company commander has therefore appointed a medical orderly whose combatant duties are nominal, and who has since been trained to teach the elementary first-aid and stretcher drill required The medical orderlies have been given the rank of corporal and are responsible to the battalion M O, with whom they constitute a committee which meets once a fortnight In each company a rota for instruction has been arranged so that each section (12 to 15 men) will in turn be taught by the company medical orderly on the weekly "platoon night" When practised in their "stretcher-bearer" duties, men are inspected in squads of four by the M O, who tests their knowledge of the following syllabus —



Splinting of fractured forearm using bayonet scabbard, handkerchief and field dressing

The control of bleeding and the dangers of a tourniquet The handling of fractures, and the use which can be made of first field dressings and personal equipment Carrying blankets in the closed stretcher Blanketing of casualties and the importance of warmth Stretcher drill and the importance of gentleness

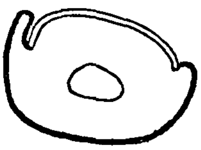
The proficient volunteers are given "S.B" brassards [illegible] the [illegible] company commanders have encouraged efficiency by making first-aid a subject for inter-section competitions By limiting first-aid equipment and the ambitions of enthusiasts it is hoped to diffuse throughout the battalion the little learning which is not a dangerous thing It may even be life-saving if circumstances should make the unofficial assistance of A R P parties unavailable

I wish to thank Mr C Du Pontet for drawing the diagrams

Oxford H C HARLEY

INGROWING TOENAIL

SIR,—I suggest the following explanations of Mr Ridley Smith's difficulties in accepting the view that tight shoes are the only cause of this condition The big toenail which is curved in the horizontal plane is doubtless an hereditary peculiarity It is the tight shoes, the inner margins of which slope to a point, which increase the natural curvature of the nail by pressure It is this pressure which folds the inner margin of the nail downwards The outer margin of the nail is usually less affected From the front the appearance is as shown (see figure) The frequency of the condition in young adults can be explained by the peculiar vanity of youth They are prepared to suffer to be—as they think—beautiful Though medical men see more cases in males, it is probable that chiropodists see more cases in females I suggest that Mr Radley Smith's case of bilateral double-sided ingrowing toenails in a youth after 11 months rest in bed can be explained by the absence of the normal upward pressure on the ball of the toe in walking This would allow the toenail to assume an exaggerated downward curve I presume that this man's toe and fingernails are of the curved variety



Bridlington P D H CHAPMAN

PLUMP TYPE OF GRAVES'S DISEASE

SIR,—May I add a word in support of Mr Geoffrey Keynes regarding the impossibility of distinguishing the plump type of Graves's disease described by Dr Trotter and Mr Eden Not all patients with Graves's disease lose weight and some are plump in spite of a raised metabolism, but the suggestion that this is especially apt to occur in young women with a particular combination of physical signs is largely hypothetical and might lead to serious misapprehension if taken for gospel, in view of the authors' claim regarding prognosis and treatment A progressive decrease in body weight is, of course, one of the best indications that the patient with thyrotoxicosis is losing ground and usually indicates the need for thyroidectomy Conversely gain in weight suggests that there is little immediate risk of physical exhaustion, but it can hardly be over-emphasised that when prognosis and treatment are under consideration such changes in body weight must be interpreted in relation to all the other clinical data available In this assessment of the case skill and judgment are required no less than in thyroidectomy In view of Mr Keynes's final remark it seems worth stating that a high mortality is not a necessary accompaniment of a surgeon's early efforts at thyroidectomy

Westminster Hospital FRANCIS F RUNDLE

STUDENTS ADVISE THE PRIME MINISTER

SIR,—I received the following telegram at the House of Commons on Oct 11 —

> We are seriously disturbed at the present military situation in Russia and are alarmed at the absence of effective British intervention We urge the Government to take immediate armed action to relieve the pressure on our Russian Allies, believing that the battle for Russia and the battle for Britain are inseparable —63 U C H STUDENTS

I understand from notices in the press, which has given the incident wide publicity, that the same telegram was sent to the Prime Minister and to the Secretary of State for War The signatories are presumably, present or prospective constituents of mine, and I would like to thank them for the compliment they pay me in addressing me The telegram is unsigned, so that a direct acknowledgment is difficult The primary pur the telegram is obviously to exert pressure upon Prime Minister to take action which seems desi the signatories, unacquainted as they must be with the considerations that are weighing with the Minister May I suggest an analogy which will I persuade the signatories that their intervention is advised ? Let us suppose that the operating thea a great hospital school is filled with first year m students, assembled to watch the most famous sur of his generation perform an exceptionally cr abdominal operation The surgeon on opening abdomen finds conditions in which, his unique ex ence tells him, completion of his operation may b immediately fatal results The surgeon paus reconsider the situation, and the students unable to what he sees or to gauge its significance, shout at "For goodness' sake, man *do something*, if only to re our unbearable suspense" The Prime Minister r the position of this surgeon, and I submit that decision for which he and not his critics, is respo should be left to his unfettered and consummate j ment

House of Commons E GRAHAM LITTLE

"FIRST-AID TO THE INJURED"

Dr JOHN C HODGSON, battalion medical officer to Kent Home Guard, has sent the following letter to the secretary of St John Ambulance Association —

SIR,—For the last fourteen years it has been my pleasure and privilege to lecture and to examine on behalf of your association While I have always thought that your authorised textbook "First Aid to the Injured" is extremely satisfactory as a training manual in time of peace, my studied opinion during the last three years has been that it is inadequate in time of war, when the basis of first aid must b simplicity, flexibility and improvisation

In peace the interval between the accident and the casualt receiving professional attention has been measured in minutes, in war, and more particularly during a period of invasion, the interval may be one of days This is especia true in the rural areas, where the only skilled help availa for casualties, even for as long as ten days, may be St J and Red Cross personnel, working in isolated houses with any surgical supplies, or in the casualty collecting po the Home Guard, and A R P points and posts, with li supplies of dressings

I would therefore appeal to your association to con whether a supplementary pamphlet on "First Aid in Wa time" should not be considered an urgent and imme necessity My tentative suggestions would be that hæm rhage, shock, wounds, fractures, pain and burns, and t evacuation and removal of casualties are the necessary jects for reconsideration, with particular emphasis on the and abuse of the tourniquet The immediate reaction of t first aid student to the treatment of bleeding should r the tourniquet—it is not a foolproof weapon

*** In a leading article in THE LANCET of Jan 25, 1 it was pointed out that the St John and Red Cross t books were neither of them designed to meet the type problem presented by air-raids and the former is dire to peace-time conditions First-aid is unsatisfac at present because it is badly taught and an es support of teaching is a textbook based on re conditions —ED L

TWO NEW GLAXO PRODUCTS —Glaxo Laborato have sent us particulars of their two new produ In NICORBIN tablets 1 mg aneurine hydrochlor 25 mg ascorbic acid and 10 mg nicotine acid are c bined for treatment of subclinical multiple defici states and for protection against beri-beri, pellagra scurvy Nicorbin is designed as a therapeutic a and except in gross undernourishment is not inten as a dietetic supplement

High-potency OSTELIN capsules each contain 100,0 international units of vitamin D (calciferol) in veget oil solution This strength allows small-bulk ad tration of the massive doses (e g 150,000–600 000 daily) used in Stoss therapy (*Lancet*, 1938, 1, 6 High-potency Ostelin tablets containing 50,000 i u continue to be available for the time being

Obituary

ROBERT BRIGGS WILD

M D LOND , M SC MANC , F R C P

death of Dr Robert Wild, formerly Leech pro- of materia medica and therapeutics, will bring memories of old times and old friendship to genera- of Manchester medical students He was a ning examiner, and nervous students must often have been grateful to him for friendly encouragement and for keeping enthusiastic external examiners within bounds In the last war he was a general favourite in the 2nd Western General Hospital, mixing well with the officers who were continually joining and leaving the staff and always willing to tackle any job that came his way

Coming from Holcombe, near Bury, Wild joined the medical school in 1880 and from that time till his retirement in 1927 was connected with it in one way or another er serving as house-physician and pathological regis- at the Royal Infirmary he worked in the department pharmacology with D J Leech, and on his death ceeded him in the chair He wrote many useful icles which illustrated his practical experience with gs and he was specially interested in ointments and in gs which deaden pain The layman was grateful his willingness to try out every remedy that had a uted action for good on cancer To both the nchester and Salford Skin Hospital and the Christie ncer) Hospital he was a devoted servant In the versity he held, in addition to his professorship, the ntions of pro-vice-chancellor and dean of the medical ulty He also represented it on the General Medical ncil for five years On his retirement he presented the university £250 for endowment of a prize in rmacology and at the same time received from his old dical friends his portrait by Francis Dodd reproduced e , this he passed on to the medical school Wild s a keen antiquarian, and he and his wife, who was laughter of Colonel Hillkirk of Withington, gave to etham's Hospital an old street cross, Hyde's cross, which one time stood in one of Manchester's busiest spots Lately Wild had lived in Buxton, where his wife parently in fair health died suddenly seven days fore his own death on Oct 7 He was nearly 80 They d been married fifty-four years They leave two ughters, the elder one a doctor who married Dr E R gger of Burton-on-Trent

OTFRID FOERSTER

IT will be a grief to many to learn that they will not et Otfrid Foerster again He was the best German neral neurologist since Oppenheim, but he was more— was the most important neurophysiologist that rmany has ever had and would have been regarded a great acquisition by any university in the world lucated at Kiel he went eventually to Breslau to serve der Wernicke He was early interested in muscle nus and this led him to his well-known work on izotomy This work illustrated his power to extract fullest number of facts from a single happening, for addition to his studies on the resulting hypotonus he served segmental flushing from stimulation of the inal roots, and years later published the best documented per on the extent of the spinal dermatomes that has peared For many years he was a spectator in sur- al procedures, many of his early operations being ne by Küttner The war of 1914–18 brought him portunities to operate himself, and some of his best ysiological work also came out of it—his observations peripheral nerve and spinal injuries During the last years he became more and more interested in brain echanisms in cortical stimulation, in the surgical eatment of epilepsy, and in intracranial tumours operating himself The book which exhibits his qualities at their best is that on the pain pathways Recently in collaboration with Bumke he edited the great "Handbuch der Neurologie," to which he contributed several important sections, notably those on the motor and sensory cortex The Rockefeller Foundation built for him in 1934 an institute for brain research in the Wenzel Hanke Hospital, where much of his work had been done

All of Foerster's work showed a strong physiological bent , he was probably a better experimentalist than doctor Patients were to him damaged units needing repair, but he preferred them to repay him by contributing to the knowledge of nervous mechanisms He had good reason to demand it, for few clinicians have had more penetrating insight or chosen with greater acumen the methods that would best resolve a problem The mark of a scientific mind is to see a problem, to estimate whether it is complex, and then to devise means of solving it None of these is easy Foerster had a gift for them all A striking feature of all his work is the excellence of his illustrations, betokening his insight into requiredness as well as his artistry He was an intensely interesting man, a good talker, with a memory highly retentive of difficult facts, and a kind and hospitable man who loved to have his pupils to his house once or twice a week, where they sat till late drinking his special brands of Rhine wine and pink champagne while he talked of everything—neurology history, poetry, even politics He had been selected by the German government to attend Lenin in 1920 (a fact that a later government thought discreditable) and found him an extremely interesting personality Foerster had inherited from his father, who was professor of rhetoric in Breslau, considerable histrionic gifts and a love of literature, especially of Goethe, pages of whose poetry he knew by heart He was an admirable speaker, and his sense of timing and of the fitness of certain words and gestures for special occasions made his public appearances always remarkable His spare figure, his pale features, his carriage, all combined with his words to make his hearers realise they were in the presence of a great man Those who knew him more intimately felt at once the emotional warmth which his keen scientific mind half obscured They will deeply regret the ending of their friendship with a rare character, and a distinguished man

G J

WILLIAM KERR RUSSELL

M D DURH

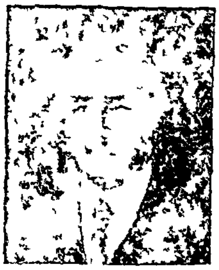
Dr Kerr Russell, who died on Oct 4 in hospital at Oxford after a short illness, was the son of Dr Frank Russell of Heaton, Newcastle-on-Tyne He went to Quaker schools at Ackworth and York and then to the Durham school of medicine from which he graduated with first-class honours in 1914, being awarded the Goyder scholarship After serving four years with the R A M C he had good surgical experience under Rutherford Morison in orthopædic work before entering general practice in an industrial district of Newcastle where he was joined by Eleanor Wylam, a fellow Durham graduate, whom he married in 1923 Their bent was towards physical methods and Russell founded the Sun Ray Clinic of which he was honorary director until he left Newcastle for London in 1928 to take up specialist practice in physical medicine He was given charge of the light and electrical departments of the Miller Hospital and in 1934 became hon physician to the National Temperance Hospital where he reorganised the physiotherapy department At Harrow where they lived he and his wife were joint hon physiotherapists to the local hospital He was at once shy and sincere, with that sort of enthusiasm for his job which makes for experiment and advance His shyness may have been coupled with his slight deafness but colleagues who came to know him well learned

to value his good humour and his skilful collaboration in treatment, as well as his vitality and vision At the Miller where some 75,000 treatments were given in the year, he was co-director of the Almeric Paget school, lecturing to students of massage This considerable clinical work did not prevent him from making a world-wide study of physical treatment, reflected in the *British Journal of Physical Medicine* of which he ultimately became editor, and in two popular books on ultra-violet radiation, one written in collaboration with his wife In June 1940 Russell left London to take over single-handed a country practice at Ross-on-Wye and after a strenuous twelve months there had the first premonition of the deep-seated glioma which so rapidly proved fatal He was in his 51st year and is survived by his wife a son and a daughter

ALEXANDER GOODALL

M D EDIN F R C P E

Dr Alexander Goodall, senior physician to the Royal Infirmary, and past president of the Royal College of Physicians of Edinburgh, died at his home on Oct 7 Dr Goodall, who was a son of the manse, was born at Barr in Ayrshire in 1876 and educated at George Watson's and at Edinburgh University where he graduated M B in 1898 and M D with high commendation in 1901 He became an assistant physician to the Royal Infirmary in 1913 and physician in 1928 on the retiral of G L Gulland, with whom he collaborated in his book on " The Blood " In his early days Goodall worked with Noel Paton and from 1906 till his death he was lecturer in physiology in the School of Medicine of the Royal Colleges He had been elected to the fellowship of the Royal College of Physicians of Edinburgh in 1904, and from 1937 to 1940 he was their president For many years he was one of the busiest consultants in Edinburgh, and he maintained his close interest in hæmatology on which he continued to give postgraduate lectures after he had retired from his lectureship on clinical medicine at the university During the last war Goodall served in the R A M C as major in charge of a medical division at Salonika, and he often spoke of the value of this clinical experience Dr Goodall is survived by his widow, two sons, and three daughters



Swan Watson Edinburgh

Dr Fergus Hewat, who shared with Dr Goodall for seven years a ward in the Infirmary, writes Goodall was a shy man and disliked medical committee work where discussions are apt to be prolonged and tedious, and he was happier teaching and looking after his patients

He loved his home and his children, and for some years was proud to be the only grandfather on the staff of the Royal Infirmary He found time for shooting, and on his day he was an excellent shot He loved the country and all its associations He always tried to see the humorous side of a situation, and this outlook at times led him to be misunderstood by those who were more formal in their demeanour, but the big occasion made no appeal to him

JAMES RUSSELL McWHIRTER

M B BELF , ACTING SQUADRON LEADER R A F

Dr McWhirter was born in 1909 and educated in Belfast, where he qualified in 1934 After holding house-appointments at the Royal Infirmary, Bristol St Luke's Hospital, Chelsea, and Archway Hospital, Highgate, he was appointed to a short-service commission in the Royal Air Force in 1937 During the next two years he served at various flying training schools and qualified as a pilot in 1939 Early in 1940 he was posted to Middle East Command, and shortly afterwards he was transferred to the reserve on completion of his initial service on the active list He remained employed as a reserve officer, and he was serving in the Coral Zone when he was killed in a motor accident on Aug 31

NAVAL HONOUR —The D S C has been awarded to Surgeon Lieutenant E A. Penn, M R C S , R N , H M S *Ladybird*, for courage and coolness when his ship was sunk by enemy aircraft

Public Health

From the School Reports

CUMBERLAND

Dr Kenneth Fraser in his school report for 1 that the evacuees were better nourished, especi school-leavers, but less clean than the native children of the second large evacuation in mid 1940 were less unclean than those of the first eva in 1939 and gave little difficulty in billeting. Of native children 5% were ill nourished in infants, i intermediates, and 5% in leavers Amongst the ev the percentages were 3, 3 and 1 Whatever may value of the standard adopted it was uniform, so the sets are comparable There may have been selection in the evacuees , or it may be that the diff is partly racial—e g , that the evacuated children come from the cities develop more quickly than country folk—and it is not possible, especially in leavers, to distinguish malnutrition from the r growth which occurs about puberty But there always been something to explain about the nut of the children of Cumberland The cleanliness of 1940 evacuees compared with those of 1939 is exp by " the commotion incidental to the outbreak of war the one hand and the prepared evacuation of 1940 Owing to the widespread reservoir of the head louse, heads of school-children can be kept free from ve only by constant action In the upset at the start of t war supervision was much more faulty in the evacuat than in the receiving areas and this accounts in part for the high infestation of children on reception

LEICESTERSHIRE

Dr J A Fairer tells us that in the routine inspection of 12,303 children during 1930 441 were referred for treatment for tonsils alone, 118 for adenoids alone 361 for both tonsils and adenoids This incidence is lo The percentage of children referred for tonsillectomy varied enormously in different places and at diffe times, but that referred for adenoids has declined ste The fluctuations of tonsil cases may vary with f or individual opinion, but the incidence of adenoids which fashion has played no part and opinion is divided, must reflect a true decline of the ad syndrome which has been obvious in recent y Indeed the running nose, both a cause and a symptom adenoids, is now seldom seen This is probably due improved nutrition and is one explanation of the droplet infections in circumstances otherwise favo to a high incidence. Among the inspected children two cases of crippling rickets were detected '

Infectious Disease in England and Wales

WEEK ENDED OCT 11

Notifications —The following cases of infectious di were notified during the week smallpox 0, sca fever, 1336 , whooping-cough, 1970 , diphtheria, 10 paratyphoid, 64 , typhoid, 23 , measles (exclu rubella), 787 , pneumonia (primary or influenzal), puerperal pyrexia, 145 , cerebrospinal fever, 1 poliomyelitis, 38 , polio-encephalitis, 4 , enceph lethargica, 2 , dysentery, 207 , ophthalmia neonato 89 No case of cholera, plague or typhus fever notified during the week

The number of civilian and service sick in the Infectious Ho of the London County Council on Oct 8 was 1304 , inc scarlet fever, 160 diphtheria 270 measles, 23 , whooping- 524 , enteritis, 27 , chicken pox 17 , erysipelas 29 , mump poliomyelitis, 7 dysentery, 16 cerebrospinal fever, 17 , pu sepsis 12 , enteric fevers 48 malaria, 1 , other disea infectious) 45 , not yet diagnosed 97

Deaths —In 126 great towns there were no de from scarlet fever, 1 (0) from enteric fever, 3 (0) fr measles, 9 (3) from whooping-cough, 34 (0) from di theria, 42 (3) from diarrhœa and enteritis under 2 ye and 11 (0) from influenza The figures in parenth are those for London itself

Preston reported a fatal case of enteric fever There w deaths from diphtheria at Birmingham In the same week Bi had 30 deaths from diarrhœa

The number of stillbirths notified during the week 207 (corresponding to a rate of 39 per thousand t births), including 11 in London

Notes, Comments and Abstracts

ALTH EDUCATION BY PROPAGANDA

GEOFFREY BARBER, M B CAMB

announcement by the Chief Medical Officer of a -wide campaign against the common cold comes spur to those who have already been planning an wider campaign against all diseases which can be prevented or lessened by fairly simple measures uccess of the Ministry of Food in teaching the public t economy in the kitchen, and the essentials of hy feeding, through what is called the Food Front, prompted the question whether a similar Health t might not be equally successful The same iods could be employed—posters to draw attention lvertisements in the press, and a daily short broad- at a popular time All three would be used in t collaboration, being planned by one source to rtise and fit in with the other two The posters the press would use slogans and cartoons, such as on't belong to the sixth column of disease" and the ices of Fougasse for cartoons of the German leaders arious unhealthy rôles could be relied on to fix the ular imagination where it is wanted

roadcasting on health is at present limited to a t talk on Fridays at 10 45 A M, and this is not ugh, besides being at a time when few can listen eed, it is shown to have only 6% of listeners These s are independent of the few sporadic press articles advertisements which do appear from time to time, reas a short daily talk at a popular time, advertised he press and led up to by cartoons, could do powerful k The talks would have to be very carefully nned, and there are many errors and pitfalls to be ided It is difficult to talk on medical subjects and p one's language simple and free from technicality, l the speakers would have to arrange not to contend h or contradict each other Above all, the talks ld have to avoid suggestions which might encourage hypochondriac and fusser The subjects of the short adcasts might be as follows

he scope of medicine, preventive and curative

iseases which are definitely preventable—smallpox, hoid, diphtheria, tetanus

iseases which *may* be prevented—bovine tuberculosis, oping cough, impetigo

hose which may be lessened, chiefly because they are ried by droplet infection or by dust—tuberculosis, sillitis, scarlet fever, influenza, colds and coughs

he natural history of the house fly and its bearing on some esses

The influence of crowds, sneezing and coughing in public a form of sabotage Cinemas and tubes

What the public has a right to expect of medicine, from eral practitioners, clinics, specialists and hospitals, and to help them to help the public (There is a good oppor- uty here to mould opinion towards necessary reforms)

The home medicine chest, and simple first aid to minor cuts, ns and sprains What a disinfectant aims at, when to it, and when to leave well alone

During illness, nursing, prevention of spread of infection

Popular fallacies, hypochondriacs and pessimists

A further series of subjects could be drawn from akespeare's seven ages of man The mewling infant m before birth, through feeding (natural and artificial), far as teething (The kitchen front has already given del talks on this, and Dr Charles Hill might well be ought back to the health front to continue right ough) There follows the schoolchild—bow legs and ock-knees, rickets, teeth—on to adolescence and berty The difficult child, and the parents share, uld be very helpful to some, particularly in small nilies Infectious fevers, and common sense in rsing them, would help parents and doctors alike emarriage and the wild-oats stage would need cautious ndling for the more prudish listeners, but if the talks l away with the present ostrich-like attitude of many rents they would prevent much hidden mental worry d suffering, venereal disease will not grow less until is treated in a more matter of fact way The need of reation for the worker, both the wage-earner and the usewife, would help the family doctor as well as the workers themselves, merely by reiterating the advice which we have to give so often; and the same applies to the many problems of middle age, obesity, rheumatism, D A H, septic teeth, and "40–50" Finally a sane word or two might be said on the stages of "slowing down," and "packing up," to try to instil a reasonable attitude to death and comfort the cancerphobe

Facility in broadcasting does not always go hand in hand with the best knowledge on a subject, and it would be wise to coordinate the efforts of all the speakers by making them prepare their talks in the same way, so as to ensure an easy style The following routine has something to commend it First write down all your ideas on the subject; classify and arrange them and make them into a short continuous essay Then make a precis of your essay, with headings and notes, and finally use this as a basis for a conversational talk to your shorthand typist This method will often produce a fluent and unstilted talk from a man who thinks more easily than he speaks

MILK FOR INVALIDS

THE arrangements for the supply of fresh milk on a priority basis to certain classes of invalids have now been completed Lord Horder, as medical adviser to the Minister of Food, has sent a personal letter to each registered medical practitioner enclosing a confidential statement regarding the issue of medical certificates for the supply of milk on a priority basis under the milk supply scheme These two documents explain the reasons for the special arrangements and detail the conditions and procedure governing the issue of certificates for liquid milk to people suffering from any of the prescribed medical conditions Under the arrangements as finally agreed, the doctor will insert on the certificate the class number and letter of the medical condition according to the schedule in the confidential statement, otherwise no diagnosis appears on the certificate In this form the certificate will fully preserve the *confidential relationship of patient and doctor* The certificate passes direct to the local food office, which issues the necessary documents to permit the supply and purchase of the prescribed quantity of milk for the period authorised These arrangements impose on members of the medical profession sole responsibility for the issue of medical certificates for milk in accordance with the Milk (Scheme of Supply) Order The conditions qualifying for priority cover a wide range, and Lord Horder urges that a certificate should only be given where genuinely necessary "If the maximum allowance is prescribed in every case of illness," he says, "the total consumed in this way may seriously curtail the supply of milk available for able-bodied adults, and even prejudice the quantities needed by mothers, children and adolescents"

CHILDBIRTH IN DUBLIN

THE reports [1] of the Dublin maternity hospitals (the Rotunda, Coombe Lying-In, and National Maternity) for 1940 cover records of over 11,000 patients The cases are tabulated without the familiar division into booked and unbooked, which is usually made to show the benefit of antenatal care Certainly the cases "from the country" include the bulk of those in poor condition, bad subjects for necessary operative interference At the Rotunda, 80% of the patients made antenatal visits and Coombe Hospital reports 2 6 visits per patient Delivery was per vaginam in 10 Rotunda patients who had previously had cæsarean section; 2 of the babies died, 4 similar cases were successful at the Coombe That there is a danger of rupture of the scar is shown by the record of a case treated by hysterotomy for hyperemesis, she had mild albuminuria in a subsequent pregnancy and was given three doses of pituitrin, 0 25 c cm, with resultant rupture treated by immediate cæsarean and repair One case of ruptured scar at the Coombe Hospital was treated by cæsarean hysterectomy In another case a premeditated repeat cæsarean revealed a scar deficient for 1½ in, covered only by peritoneum, which had remained intact in the absence of labour pains

Local anæsthesia is used for some cases of cæsarean section, 4 of the 63 operations at the Rotunda were by this method, and 8 of the 41 at the Coombe Upper

---

[1] *Irish J med Sci* August, 1941 p 273

and lower segment operations were performed in the ratio of 14 to 49 at the Rotunda, 16 to 25 at the Coombe, and 3 to 34 at the National Maternity Cæsarean hysterectomy was twice considered necessary at the Coombe—for ruptured scar, and toxic accidental hæmorrhage After 3 of the 63 cæsareans at the Rotunda "burst abdomen" followed on within 7–10 days, one case proving fatal The 3 patients were suffering from concealed accidental hæmorrhage, hæmatoma of the rectus sheath, and pre-eclampsia At the Rotunda, 2 successful cases of pubiotomy are recorded In both the pelvis was contracted, and the operation was performed to facilitate delivery with Kielland's forceps, the operator having been unsuccessful without it The patients were discharged walking, on the 10th and 16th days, and both infants survived

Cases classed as eclampsism in the Rotunda report seem to include chronic nephritis The group consists of 7 multiparæ and 3 primigravidæ, 4 of the 10 cases had a blood-pressure of over 200 mm Hg with albuminuric retinitis, and were less than 30 weeks' pregnant The eclampsia group, on the other hand, contained 9 primigravidæ and 2 multiparæ, only one case being less than 37 weeks pregnant In the treatment of eclampsia the Coombe Hospital uses lumbar puncture, and the intravenous injection of 50% glucose, while the National Maternity uses magnesium sulphate injections, details of the methods are not given The three hospitals treated 42 cases with 2 deaths Flourishing gynæcological and pædiatric clinics are attached to the hospitals, and are an asset for teaching purposes In following up mothers and babies the student sees just the kind of case he will have to deal with in practice Of the hysterectomies performed, 50% at the Rotunda were by the vaginal route, but only 1 in 30 at the Coombe, and 9 in 59 at the National Maternity

C S M M G SALARIES —In a recent issue (Oct 11, p 441) it was stated, on the authority of the secretary of the Chartered Society, that the new scale of salaries recommended by the council for members of the society working in E M S hospitals had been approved by the Ministry of Health We understand that this approval has not gone beyond the readiness of the Ministry (set out in E M S Gen 330) to reimburse these hospitals for the usual proportion of the work done there by auxiliary medical services

University of Wales

Dr D T Thomas has passed the examination for part II of the D P H

Royal College of Surgeons of Edinburgh

At a meeting of the college on Oct 15, with Dr H M Traquair, the president, in the chair, the following were admitted to the fellowship —

W V Beach, M R C S, D W Bracey, M B Lpool, M S Campbell, M B Lond, Iqbal Chand, M B Punjab, C D Coode, B M Oxfd H K Dastur, M R C S, Hiren De M R C S J C Dick, L R C P E, H L Duncan, M B Edin M G el Din, M B Cairo Thomas Gibson, M B Glasg, W H Kirkaldy Willis M B Camb, M A M Labib, M B Cairo, H A McDonald, M R C S, W C McGuire, M D Ontario, George MacKay, M D Manitoba, J W Morgenthal, M B Edin and J M H Ross, M B Edin

The following office bearers were elected for the ensuing year president, Mr J W Struthers, vice president, Dr H M Traquair, secretary and treasurer, Mr K Paterson Brown, members of president's council, Mr James M Graham, Prof R W Johnstone, Sir John Fraser, Mr A Pirie Watson, Dr G Ewart Martin and Mr Francis E Jardine, representative on the G M C, Mr Alexander Miles, convener of museum committee, Mr W Quarry Wood, and librarian, Dr Douglas Guthrie

CORRIGENDA —For M D Edin read M B Edin in the title to Mr Winsbury-White's article (Sept 20, p 331) —On p 453 (Oct 18), fourth line from the end, read *saline* for *normal-saline*

Radiology under Social Security

A New Zealand correspondent writes In August di services in the X ray departments of public hospitals made free to all, as therapeutic services had already been This cleared up the anomaly that existed since hospital fits were introduced, namely that it cost a patient say guineas as an outpatient of a public hospital to have his or stomach X-rayed, whereas if he got himself admitted a inpatient for a few days the whole cost him nothing T expected flood of work has not fully materialised though quite clear that the volume will be considerably increa Particularly in the larger hospitals, staff, room and are not nearly adequate for present needs, working under conditions, let alone extra demands Radiologists in priv practice are to be allowed to claim from the Government same sums per service that are paid to the hospitals for X work These are detailed in a Schedule and are expecte under N Z conditions in private practice, to cover costs o Radiologists will require to be recognised for the purpo the Government and will be allowed to charge further to the patient over and above the sums mentioned F details of the Government allowances, and extras charges remain to be fixed The arrangements were passed in Parl ment before the radiologists commented on them It believed that a firm of dealers in radiological equipment and hospital secretary advised the Government The radiologis met soon after the enactment, and are now conducti negotiations with the Government

Royal Society of Medicine

On Monday, Oct 27, at 2 30 P M, Mr *Harold Round* M D S, will give his presidential address to the section of odontology He will speak on the value of a dental depart ment in a general hospital On Saturday, Nov 1, the section of physical medicine will meet at Bath There will be clinical demonstrations at the Royal National Hospital for Rheumatic Diseases at midday, and in the afternoon a demonstration of hydrotherapy in the Royal Baths followed by a discussion on its value in rehabilitation

Appointments

FORGACS, PAUL, L R C P temp asst M O for Buckingham
PHILLIPS, T J M R C S temp asst ophthalmic surgeon to t Liverpool Eye, Ear and Throat Infirmary

The Chief Inspector of Factories has appointed the follow examining surgeons

ABBAT, P D M B Manc for Ludgershall, Wilts
HAWKE R F L M S S A for Crawley, Sussex
KNOWLES, R R, M B Lpool for Birkenhead, Cheshire
McDONALD, CARRICK, M B Glasg for Kilwinning Ayrshir

OME PROBLEMS OF WOUND INFECTION *

A A. MILES, M A CAMB , F R C P
ROFESSOR OF BACTERIOLOGY, UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL

E H Kettle once deplored the dominance of the acteriologist in the study of infective inflammation—a ominance which he felt not only elbowed out the more rofitable study of the host's reaction but also obscured he problem with so many irrelevant facts about bacteria hat the wood could not be seen for the trees (Kettle 1927) This lecture is an attempt to show how much the " dominnt bacteriologist " has contributed to the study of wound nfection , his contribution is extensive and significant, out has been more successful in prophylaxis than in cure

EARLY AND LATE INFECTION COMPARED

The bacteriologist is, in the first place, faced with freshly inflicted wounds In them he finds bacteria apparently derived from skin, alimentary tract clothes and surrounding dirt The cultivation of swabs from very early wounds yields mainly indifferent cocci, both staphylococci and streptococci, diphtheroids, aerobic spore-bearers of the *Bacillus subtilis* type, and anaerobic spore-bearers Later swabs yield a greater variety · for example, 1–3 days after infliction, wounds contain *Streptococcus pyogenes* and *Staphylococcus aureus* in addition to the bacteria already mentioned The increase may in part be due to the growth of small initial doses of bacteria into recognisable prominence But figures for swabs taken 4–12 days, and 13–30 days after infliction show that while spore-bearers and indifferent cocci die out there is a still greater incidence of *Strep pyogenes*, *Staph aureus* and *Pseudomonas pyocyanea* The incidence of coliforms remain relatively high It is, in fact, the frankly pyogenic bacteria—streptococci, staphylococci and the coliforms—which appear in the later cultures (Miles et al 1940, Spooner 1941) These newly appearing bacteria may have been introduced at the time of wounding or added later If we assume that all the bacteria in a wound grow from small numbers introduced at the time of wounding, we shall have difficulty in explaining why *Staph aureus* and *Strep pyogenes* often appear for the first time as late as 3 weeks after wounding, for they are not given to lying dormant in the tissues It is easier to maintain that they are added after the infliction of the wound , and indeed, particularly in the case of the streptococci, we have strong circumstantial evidence in support of it The pyogenic streptococci can be subdivided by serological tests into a number of well-defined types In civilian life they reside in the upper respiratory tract of some 5–10% of the population, and if we were to select a few hundred people in a haphazard fashion, we should find that their throat streptococci belonged to a wide variety of types , no one type would predominate But when 50 of these wounded people are gathered from different places into one ward, not only may as many as 40% be infected with streptococci but the streptococcal types are not distributed in quite so haphazard a manner as we might expect had they been picked up from the environment at the time of wounding certain types predominate, which suggests an infection from a common source Moreover, a predominating type often turns up late in the history of wounds under treatment in a single ward, and by keeping a close watch on the noses, throats, wounds and cut fingers of patients, nurses and medical staff it is often possible to trace the apparent course of infection by one type of streptococcus from wound to wound, wound to throat, throat to nurse's cut finger, and cut finger to another wound

In certain Hertfordshire hospitals we seldom found *Strep pyogenes* in wounds sampled within a few hours of infliction , yet the incidence of streptococcal wound infection in the wards varied from 20 to 70% Colebrook and Francis (1941) estimate that 5% of their burns were initially infected with *Strep pyogenes*, and found 70% infected in hospital Besides streptococci, there are added infections by *Staph aureus*, coliforms, *Proteus vulgaris*, and occasionally the tetanus bacillus, Welch's bacillus and the diphtheria bacillus It is not uncommon to find added infections of all kinds in half the wounds of a ward Not all these infections are serious or give rise to clinical signs of infection but there is evidence that (apart from the quite large numbers of patients who are made seriously or even fatally ill by added infection) many milder added infections retard wound healing and certainly increase the risk of the cross-infection of clean wounds by constituting an open reservoir of potentially pathogenic bacteria

Added streptococci originate in the nose and throats of carriers It is the skin, and especially the skin recently infected with staphylococci, that is usually regarded as the source of *Staph aureus* But it is probably truer to regard the nose as its more constant origin *Staph. aureus* may infest the deeper crypts of the skin, but on the skin itself it is a superficial transient contamination It seems clear that the nose is the source of the skin staphylococcus, since both superficial and deep skin carriers are commonly nasal carriers In a few tests of such double carriers in which a precise serological typing was possible the staphylococci from the nose and skin proved to be of the same subtype The importance of the streptococcal carrier is fully appreciated , the potential dangers of the nasal carrier of *Staph aureus* are less obvious, but none the less important in combating hospital infection, for up to 90% of the wounds in a ward may be infected with it

A rough estimate of the extent of this nasal danger may be made by piecing together the scanty information about staphylococcus carrier-rates (Hallman 1937, McFarlan 1938, Gillespie et al 1939), and including some recent surveys that Dr A C Cunliffe and Dr A M Thomas have been making in Hertfordshire It appears that the staphylococcal carrier state in the nose, far from being the result of a temporary infection or contamination, may be the result of an early colonisation of the nose that gradually disappears with advancing age The nose of the newborn child is sterile, but at 2 weeks old 90% of the infants in hospital wards are infested with *Staph aureus* The incidence drops to 50–60% in young children and to 20–40% in young adults Of these carriers, at least half are profuse, and remain so for months on end The figures are appropriate to our inquiry, for they were obtained mainly from hospital patients, staff or medical students, and may be said to represent the staphylococcal environment of a wounded person in hospital We do not as yet know whether all strains of true *Staph aureus* are equally pathogenic The common infectors of the nose may be relatively innocuous, and wound infection may be due to more rarely occurring virulent types But until we know more about the properties of the staphylococcal subtypes it is reasonable to assume that the high incidence and relative permanence of *Staph aureus* nasal carriers in hospital personnel and patients, and the consequent high skin-carrier rate, is responsible for the predominance of *Staph aureus* in the infections of war wounds It is impossible to exclude all nasal carriers from participation in surgical work But the risk of infection from them is reduced to a minimum if all those engaged in surgical manipulation of wounds are compelled to wear impermeable masks in the wards as well as in the theatre

As a result of many bacteriological surveys of wounds, it may be said that the bacteria introduced into wounds by direct enemy action are much less disabling in the sum total of their after-effects than those introduced after infliction It is also true that a great deal of this added infection is preventable In peace-time the risk of hospital infection was small, though definite But the aseptic technique of peace has not stood the strain of a war in which at any moment a base hospital may be overwhelmed with the additional duties of a casualty clearing station The surgeons were the first to set their house in order over hospital infection, and in the process became part-founders of medical bacteriology But the initiative in the fight against hospital infection has lately passed to the fever hospital and to the obstetric and children's ward, and it is to the bacteriologists who worked in these places that we owe our present impetus in tackling war wound infection The surgeon already has the prophylactic techniques at his disposal, and a rearrangement of their emphasis and application should suffice to make the wards and theatres safe

---

* Abridged from the Kettle memorial lecture delivered at the Welsh National School of Medicine in May 1941

Last year Dr Joyce Wright and I found the hospital-infection rate in a certain neurosurgical ward at times rose as high as 30% In four months, 15% of all wounds —air-raid or operation—were infected in hospital The figure was comparatively low, because a careful forceps-dressing technique was employed, but nevertheless *Strep pyogenes* was spreading from patient to patient During the air-raid lull of the new year the ward dressing technique was carefully revised Masking was rigidly insisted on during dressing, and a new routine instituted Since that time Dr Wright has maintained a detailed bacteriological watch on the whole unit The technique was maintained even when three separate convoys of air-raid casualties had filled the wards to their limit, and the result was excellent In spite of the presence of *Strep pyogenes* in chronic and newly admitted wounds in the throats of patients and staff (including an epidemic of a type 4 in the throats of 7 people), and in the air of the wards, the number of patients with added infections in a second 4-month period has been 4 Of these infections 3 were in trivial wounds of the arm and leg, which were dressed by the ordinary technique, they constitute an additional proof of the efficacy of the improved precautions, for the head wounds of the same patients were dressed by the improved technique and remained without added infection (McKissock et al 1941)

With the bacterium already established in the wound the issues are less definite Dominating the scene is the purulent wound infected with the pathogenic streptococci and staphylococci and those junior partners in the pyogenic axis—the various coliforms, *P vulgaris* and *Ps pyocyanea* It is worth noting that we have not yet exhausted the information we can get from the bacteria themselves in explaining the variations in severity of these pyogenic infections and the changes in bacterial flora that accompany healing or exacerbations of infection Next in numerical importance is the wound in which the initially infecting organisms, mostly saprophytes, die out in a few days and stimulate little, if any, tissue reaction Such wounds might be called contaminated rather than infected, and they solve their own problems by never proceeding to infection Finally, there is the wound in which essentially saprophytic bacilli find an opportunity to instigate a gas gangrene These bacilli, in the order of their frequency in wounds, are *Clostridium welchii*, *Cl sporogenes*, *Cl septicum*, occasionally *Cl œdematiens*, and a host of more or less well-defined species, all spore-bearing anaerobes I call them essentially saprophytic, for in most wounds they die out as rapidly as other contaminants like *B subtilis*, sarcinæ and micrococci In a minority of wounds they may multiply with other bacteria in a superficial necrotic layer of tissue, but it is only in a few wounds so infected that gas gangrene supervenes The opportunity for the offensive germination of the gas-gangrene bacilli is provided by areas of tissue, usually those denuded of oxygen, in which the reducing intensity, chemically speaking, is increased to a point that allows the growth of anaerobes, and this opportunity is largely removed by clearing from the wound foreign bodies, dead tissue, and anything likely to kill the remaining healthy tissue

So far there is little definite information on the importance of those differences we can detect in the strains of *Cl welchii* isolated from human flesh wounds Robertson and Keppie (1941) found that there is a tendency for *Cl welchii* strains from gas-gangrenous wounds to produce more powerful toxins than those from the merely contaminated wounds, and that the toxigenic powers of some of these gas-gangrene strains tend to be inhibited less by changes in the hydrogen-ion concentration of the media than those of the more saprophytic strains But powerfully toxigenic strains turn up in contaminated wounds, and fatal gas gangrene occurs with the feebly toxigenic strains We have found a similar lack of definite association between the capacity of toxin-free *Cl welchii* strains to resist the bactericidal power of human blood, and the capacity to produce gas gangrene Our most resistant strain came from a small granulating scalp wound that was healed in 10 days

METHODS OF TREATMENT

To combat these bacilli we have various antitoxins and a number of antibacterial chemotherapeutic agents, both natural and synthetic Of the natural antibacterial substances, elaborated by bacteria and fungi, few have received extensive therapeutic trial Gratia (1930) in Belgium and Dubos (1939) in America have both described such substances, the one from a fungus, the other from spore-bearing bacilli In this country we have Fleming's discovery of penicillin, which is powerfully antibacterial A full test of its value must await its production in large quantities It has no observable toxic effect on phagocytes in antibacterial concentrations, and its antibacterial effect is not inhibited in the presence of organic matter Its action, like that of the sulphonamides, is apparently bacteriostatic, an effect that permits the defences of the body to take adequate action against the invader (Fleming 1929, Abraham et al 1941) The synthetic antibacterial agents include the sulphonamides and the flavines The flavines are antiseptic rather than chemotherapeutic, though two, proflavine and 2 7 diamino-acridine, by reason of their low toxicity for tissues (Russell and Falconer 1941), approach chemotherapeutic rank At present we know little of their efficacy against the gas gangrene bacteria

The sulphonamides have been extensively tried in pyogenic wounds and there is little doubt of their prophylactic and therapeutic value They are inhibited to some extent by organic matter, particularly if the products of extensive tissue breakdown are present But even in the presence of pus their local application reduces the streptococci, staphylococci, coliforms and spore-bearing anaerobes in wounds There is every justification for their early employment in the treatment of such wounds, for even if they fail to destroy the bacteria they may prevent their multiplication, and thereby permit the delays in full surgical treatment that are sometimes inevitable in war In the treatment of gas gangrene there is no similar clear cut indication for the confident exhibition of these drugs The occasions for test in man have been few, and in animals the result of numerous attempts to treat experimental gas gangrene are conflicting Attempts vary in the animals used, the dose of bacteria, and the mode of applying the drug This variety is in a sense helpful, for the common features that can be abstracted from it tell us where the truth lies First, the susceptibility of the gas-gangrene bacilli in the test-tube is of a much lower order than that of the streptococci, and this low susceptibility is reflected in the animal, where the oral administration of the drugs is relatively ineffective Local therapy with the solid drug, in whose vicinity one can expect maximum concentrations, is much more effective In the second place, chemoprophylaxis, achieved by introducing the drug along with the infecting bacilli, is more successful than chemotherapy, which only prolonged the life of animals in a few cases, and in fewer cases saved it *Cl welchii* infections are most successfully treated, *Cl septique* less, and *Cl œdematiens* least With regard to the effect of the different sulphonamides, there is greatest disagreement over *Cl welchii*, in general, the best are sulphathiazole and sulphapyridine, with sulphanilamide a close second With *Cl septique* the order is sulphathiazole, sulphanilamide and sulphapyridine, with dissidents in favour of reversing the last two, and there is agreement that sulphathiazole is outstanding with *Cl œdematiens* Fleming (1941) has suggested that for historical reasons we tend to think of sulphanilamide as best for streptococci, sulphapyridine for pneumococci, and sulphathiazole for staphylococci, whereas in fact the last drug is active against all three cocci The same holds good for the gas-gangrene organisms, sulphathiazole is not merely the best drug for *Cl œdematiens*, it appears on balance to be the best drug for the whole gas-gangrene trio

Gordon and McLeod (1941) differ sharply from the prevailing trend of experiment with artificial *Cl welchii* and *Cl septique* infections They find no trace of curative action in sulphanilamide and sulphapyridine, and only a slight prophylactic action in sulphapyridine The reason for the difference does not lie in the dose of bacteria employed, which was 10 m l d, nor in the dose of drug administered It may lie in the mode of infection, for apparently the bacteria and the drugs were introduced into artificially damaged limbs, with a syringe, whereas most of the workers who report favourably on he sulphonamides infected their animals in open wounds nd applied the drug in the same spot. If this is the eason it indicates even more strongly the necessity for a maximum local concentration of the drugs, such as would follow the precise application of the powder to the open seat of infection.

Sulphathiazole appears to owe some of its local efficacy to its moderate solubility, which, lying midway between that of sulphanilamide and the more insoluble sulphapyridine, ensures that it goes into solution slowly but in sufficiently effective concentrations. All three drugs diffuse slowly through dead tissue, but as soon as they reach tissues with active circulation they are carried away by the blood-stream. This continuous drain on the central core of solid drug in the wound results in a steep fall in concentration as one passes from wounded healthy tissue. It would be reasonable, as Hawking (1941) suggests, to supplement local with oral administration of the drug and thus, by maintaining a given concentration in the general circulation, to reduce the speed of that drainage.

ANTITOXIN AND SULPHONAMIDE ACTION

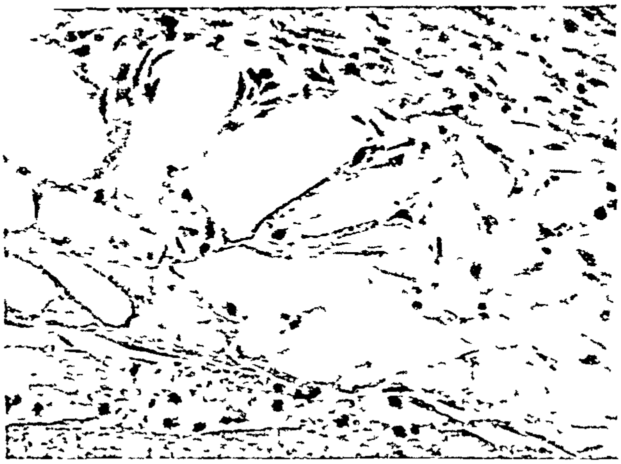
The use of antitoxin, either as an addition or an alternative to the sulphonamides, has the support of experimental work. Henderson and Gorer (1940) found antitoxin better than sulphanilamide or sulphapyridine; drug and antitoxin administered together were much more effective than either alone. Gordon and McLeod found it greatly superior to the sulphonamides as a prophylactic, and the small success they had in curing recently established infection was due entirely to antitoxin. They suggest that the antitoxin might profitably be applied locally in the treatment of gas gangrene. The analogy with local sulphonamides suggests that this would be highly effective, but we might explore the implications of this analogy before we accept it, particularly in view of the severe local reactions reported to have followed this kind of antitoxin therapy.

The effect of antitoxin and the sulphonamides on the bactericidal power of human blood for *Cl. welchii* gives some indication of their action in the body. In one experiment, for example, typical of many we have recently made an average of 1 bacillus survived from an inoculum of 4000 living bacilli in 100 c.mm. of blood. A comparatively large dose of *Cl. welchii* toxin (2 mouse m.l.d.), though it lysed the blood, depressed the bactericidal power only slightly; an average of 8 bacilli survived. But the addition of enough antitoxin to neutralise the toxin, far from restoring the bactericidal power, reduced it still more; 45 bacilli survived. *Cl. welchii* is killed in blood only in the presence both of living phagocytes and complement, and it can be shown that the combination of toxin and antitoxin, by fixing some of the complement, impairs the efficacy of the natural antibacterial mechanism. The blood-bacterium mixture is notoriously sensitive to antiseptics, yet the three sulphonamides, in a final concentration of 6.25 mg. %, depressed the bactericidal power only slightly and temporarily. After 2 hours, unheated blood kills better than sulphonamide blood. The effect is reversed in 24 hours; sulphonamides plus blood are more effective than blood alone. Leucocytes and complement contribute largely to this sulphonamide effect, for in heated blood the drugs are comparatively inactive. Penicillin in the same concentration is much more active than any of the sulphonamides, and at no time appears to affect the leucocytes. In applying these results with blood to therapy we must avoid what Kettle used to call the Bovril fallacy. The victim of this fallacy, regarding a tube of blood with the melancholy intentness of the bullock in the advertisement, and murmuring "Alas my poor brother," insists on regarding its identity with the whole body as complete. But the results do suggest that in the wound area, where the supply of blood and therefore of complement may be restricted, the local injection of strong antitoxin to settle the toxic issue might prejudice the issue between phagocytes and bacilli. Circulating antitoxin, on the other hand, which is accompanied wherever it goes by complement, is open to no such objection, and would certainly limit the specific intoxication to relatively anæmic tissues.

In this comparison of sulphonamides and antitoxin we must remember the size of their constituent molecules. The work of Menkin (1940) suggests that large molecules of foreign protein in the circulation would be selectively removed from the blood by early inflammatory tissue, and that they would be as definitely excluded from such tissue when the inflammation had proceeded to a later stage. The dye Trypan Blue behaves in the same way towards inflammatory tissue, and experiments with tissue inflamed by the *Cl. welchii* toxin show that early fixation and later rejection of the dye occur in the inflamed part. Circulating antitoxin is likely to be similarly affected; it remains to be seen whether this is in fact so, and whether the antitoxin "fixed" in the inflamed tissue is active against the toxin that produced the inflammation.

The change over from apparent avidity to inertness on the part of the local lesion may explain the enormous difference that has been observed between prophylactic and curative doses of antitoxin. In Gordon and McLeod's experiments the minimum curative dose of antitoxin a few hours after infection was 200–600 times the amount required for prophylaxis.

These considerations do not apply to the sulphonamides. A few experiments in rabbits with early and late toxin-induced inflammation show that there is no similar fixation or exclusion of circulating sulphanilamide. Presumably the molecule is small enough to be independent of these peculiar features of the inflammatory lesion; and it penetrates wherever it can diffuse, either from a deposit of solid drug, or from the circulation. Some experiments by Dr. L. E. Glynn (1941) illustrate the small deleterious effect of the solid drugs. He introduced clots of blood into pockets in the subcutaneous tissue of the rabbit and compared the organisation of the clot with and without powdered sulphonamides. Solid sulphanilamide disappeared in 24 hours. It could diffuse directly across the fascial sheath of the underlying muscle, for these were damaged to the depth of 4–5 muscle-fibres; this negligible layer of necrosis, 0.2 mm. in depth, was soon organised. Sulphapyridine produced occasional necrosis, sulphathiazole none. There were indications that sulphathiazole and sulphapyridine depressed the formation of fibroblasts to a slight extent, but the slightness is well illustrated in a section in which proliferating fibroblasts are seen actively invading the spaces immediately between the persistent crystals of sulphapyridine (see figure).



Rabbit fibroblasts growing between crystals of sulphapyridine, 7 days after introduction. (By permission of Dr. L. E. Glynn.)

It is not my primary intention to weigh the measures against infection in the balance, for there are many considerations upon which I have not touched. My survey of wound infection covers only a fraction of the ground, and much of what I have said I owe to the kindness of those who have allowed me to cite from unpublished work. Ogilvie has said that gas gangrene has its cause in a particular opportunity rather than a particular organism. If we have failed to define the opportunity we are in no position to be confident about the means of denying it to the saprophytic clostridia

2 Between 5 and 40 the survival rate is probably between 80% and 90% in the primary types, in the presence of any severe associated infection the fatality is high

3 The older age groups have a bad prognosis, there appears to be an equal chance of survival or death between 40 and 50, but after 50 survival is unlikely

4 The duration of symptoms probably has an appreciable effect on the outcome the sooner after the onset of symptoms that treatment is begun the better will be the prognosis

TREATMENT

Intensive chemotherapy should be instituted immediately on diagnosis The dosage should be adequate to provide the highest possible concentration of the drug in the cerebrospinal fluid (over 10 mg per 100 c cm of either sulphanilamide or sulphapyridine) in the shortest possible time To bring this about, the drug must be administered if necessary by all three routes by mouth, intramuscularly and intravenously (Hodes, Gimbel and Burnett 1939) It is noteworthy that, in the few series of cases reported, sulphanilamide has on the whole given better results than sulphapyridine (Schnitker 1940, Kolmer 1940) It is to be hoped that further observations will be forthcoming to explain or contradict this finding

In the age-group 5–40, except in those cases which have severe associated infections, sulphapyridine or sulphanilamide should be given in adequate dosage without specific antiserum With patients under 5 or over 40, however, it seems that specific antiserum ought always to be given Large doses should be given intravenously to combat the pneumococcal septicæmia, but there is not yet sufficient evidence to show whether it should be given intrathecally in addition Finland, Brown and Raugh suggest that it should, and the methods they advocate seem to be the most rational way of administering it They advise intrathecal injection of 5–10 c cm of the patient's own serum, withdrawn after the administration of the specific antiserum intravenously, for the provision of complement in the cerebrospinal fluid They claim that this method is least likely to give rise to undesirable reactions It is unfortunate that pneumococcal meningitis in these groups is so often fatal within seventy-two hours of its onset, making necessary the utmost speed in the institution of therapy Few institutions have the necessary antiserum on hand before twenty-four hours have elapsed, a delay which probably proves fatal to most cases

SUMMARY

In 14 cases of pneumococcal meningitis there was 1 recovery, 7 patients were over 50 and 2 under 2 years

The age-incidence of these cases and of 80 cases from the literature have been plotted to show fatalities and survivals Below the age of 1 year and above the age of 50 pneumococcal meningitis is almost invariably fatal The chief reason for the poor results in this series was probably the age of the patients

Intensive chemotherapy should be given in all cases, and specific antiserum, in addition, is probably essential for all cases under 5 and over 40

I wish to thank the honorary staff of the Birmingham United Hospital for permission to publish these cases and in particular Prof W H Wynn for his advice and criticism

PNEUMOCOCCAL MENINGITIS
RECOVERY WITH SULPHATHIAZOLE

STEPHEN J HOWARD, M R C S
LATE MEDICAL OFFICER, E M S

A BOY, aged 1 year, was admitted to the Eastern Hospital on Feb 2, 1941, certified to be suffering from measles There was a history of bronchopneumonia at 6 months He had had a cough since Jan 24, a rash had appeared on Feb 1 and he had vomited on the day of admission On examination he had a slight cough, but apart from a temperature of 100 4° F no evidence of measles or other disease was found During the next three days he remained febrile and was drowsy and moderately ill Some injection of the ear drum appeared while the lungs remained clear On Feb 5 increasing irritability focused attention on the central nervous system, although no neck rigidity could be detected Lumbar puncture revealed a purulent fluid under increased pressure, containing 1775 white cells per c cm A gram positive diplococcus present in large numbers on direct examination proved on culture to be a pneumococcus type II Treatment with sulphathiazole (M & B 760) was instituted immediately after the lumbar puncture, in doses of 0 5 g by mouth every four hours, the dose was gradually reduced over the next six days, the total amount given being 9 25 g Improvement in the clinical picture could be seen within 24 hours and in 48 hours the child was sitting up feeding himself and the temperature was falling On the 8th the cerebrospinal fluid contained 570 cells per c cm and one pair only of cocci were seen, the culture being sterile On the 17th, by which time clinical recovery had long been complete, the fluid showed only a slight cellular reaction (30 cells per c cm) His further progress was uneventful

Grossman [1] recently described an attack of pneumococcal meningitis in a baby of 3 months which he treated successfully over a long period with enormous doses of sulphanilamide and sulphapyridine, together with antipneumococcal serum He was then able to find in the literature only three authentic recoveries from this disease in children under the age of 3 years The case here described belonged to this unfavourable age-group, yet ran a comparatively mild course. How much this can be attributed to treatment is difficult to say, but improvement coincided so sharply with the administration of sulphathiazole that it is probable that this drug did modify the course of the disease This is of some importance since treatment of pneumococcal meningitis with sulphapyridine has not been uniformly successful and it may well be that sulphathiazole is to be preferred Banks [2] has indicated that the latter drug has some advantages in the treatment of meningococcal meningitis

My thanks are due to Dr Norman Begg, medical superintendent of the Eastern Hospital, for advice and permission to publish the case

CORTICAL NECROSIS OF THE KIDNEYS
COMPLICATING PERFORATED GASTRIC ULCER

B GODWIN, M R C S
RESIDENT MEDICAL OFFICER, SMITHDOWN ROAD HOSPITAL LIVERPOOL

A J McCALL, M D LPOOL, M R C P
PATHOLOGIST TO THE CITY OF LIVERPOOL SOUTHERN GROUP OF HOSPITALS

Hertzog, in 1913, described a case of bilateral necrosis of the renal cortex in a girl of 10 years who was suffering from a purulent "cryptogenic" peritonitis Few clinical details were given At autopsy no cause for the peritonitis was found, and the kidneys presented appearances similar to cortical necrosis of pregnancy It appears to be the only case recorded of this renal condition complicating peritonitis The following case was recently seen by us

Man, aged 45, admitted to Smithdown Road Hospital on March 5, 1941, with signs of perforated peptic ulcer Had been in hospital 4 years previously with 'gastritis" Urine at that time normal, and chest showed nothing of note on X ray examination

Operation (Mr R J Crompton) performed under open ether at 1 A M on 6th—9 hours after onset of symptoms—and perforated chronic ulcer on anterior stomach wall sutured itoneal cavity full of fluid under considerable pressure l containing fibrin Abdomen was closed without drain- Urine examined before operation contained trace of umin, but was not examined microscopically For re- inder of this day urine was passed normally temperature e to 99 4° F On 9th drowsiness and oliguria were noted ine contained trace of albumin, moderate number of red ls and some granular casts Blood non-protein nitrogen) mg per 100 c cm Blood creatinine 3 1 mg per 100 c cm the 10th complete anuria and coma developed Twitching limbs with irregular conjugate movements of eyes On th patient died in coma Illness had been apyrexial, cept for rise in temperature on day of operation Blood- essure was not recorded, and no bacteriological examination peritoneal fluid was made

---

[1] Grossman, A H *Arch Pediat* 1940, 57, 355
[2] Banks, H S *Lancet*, 1941, 1, 104

Autopsy (24 hours after death)—Only permission to amine the kidneys could be obtained, but the presence of a rino purulent peritoneal exudate was noted Both kidneys ere tense, slightly swollen, and presented similar appear- ices The subcapsular surface was pale and showed some techial hæmorrhages The cortex presented the opaque llowish-white appearance of coagulative necrosis A few gorged glomeruli could be seen as red specks The outline the necrotic zone had the usual serpiginous form, and tended centrally into the interpyramidal cortex The nction between normal and necrotic tissue was not notably peræmic The medulla, pelvis and larger branches of the nal vessels appeared healthy

Histology—Staining by hæmatoxylin and eosin, Weigert's rin stain and a modification of Mallory's aniline blue endrum and McFarlane 1940) The cortex showed almost nfluent coagulative necrosis involving both parenchymatous d interstitial elements There was, however, a continuous bcapsular band (0 25 mm wide) of normally staining tissue, id small, radially arranged islets of cortex were preserved, rticularly in the juxta pyramidal region Glomeruli in the ecrotic areas showed complete absence of nuclear staining, id engorged, widely dilated capillary loops Fibrin thrombi ere frequently present in glomerular capillaries Erythro- tes, with or without fibrin, were found in a number of the psular spaces Less severely affected glomeruli showed milar engorgement but with preservation of the nuclei hese glomeruli were not demonstrably larger than measured rmal controls (150μ) Slight proliferation of the tuft dothelium was occasionally seen in these surviving glom- uli In one or two the capsular epithelium was swollen id prominent, but was never more than one layer thick o hyaline fibrils were distinguishable in the tufts A few omeruli in the peripheral cortex showed slight thickening the capsular basement membrane, and one small cyst was en A number of glomerular afferent arterioles and intra- bular arteries contained fibrin thrombi In the latter the rombi were often mural in type, and fibrin infiltration was ident in the walls of one or two of these vessels The tertubular capillaries in the necrotic zone were packed ith polymorphs, a few of which had extravasated Very casional hyaline droplet degeneration, and numerous lbuminous casts, sometimes containing red-cells, were seen the medullary tubules

DISCUSSION

Mechanism of cortical necrosis—There is now fairly eneral agreement that the necrosis is ischæmic in origin ut opinion has differed as to the exact level in the renal asculature at which obstruction first occurs The iews held by different observers have been reviewed by unn and Montgomery (1941) From their own careful bservations they conclude that the primary lesion is an xtreme dilatation of the glomerular capillaries The onsequent loss of plasma leads to inspissation of the lood, stasis and finally to complete arrest of the lomerular circulation As a result thrombosis may ccur in the glomeruli, afferent arterioles and intralobular rteries, in that order In this way varying degrees of farction are produced In the early stages the pressure the arterioles and arteries is increased owing to the istal obstruction and fibrin is forced into the vessel alls, producing the fibrinoid necrosis which is often een In those cases which are associated with preg- ancy it seems likely that vaso-spasm precedes, and pro- ably determines, capillary paralysis and dilatation

Non-pregnancy cases—Dunn and Montgomery des- ribed 8 cases of renal cortical necrosis, none of which as associated with pregnancy, and found a further 18 in the literature It has been shown experimentally that *Staphylococcus aureus* toxin can produce cortical necrosis of the kidney (Von Glahn and Weld 1935, de Navasquez 1938), and in a number of non-pregnancy cases a bacterial toxin seems to have been responsible. Thus Hertzog's case followed a purulent peritonitis In our case the peritoneal fluid was not examined, but peritonitis was present In the cases reviewed by Dunn and Montgomery, scarlatina, sore throat, postoperative streptococcal infection, pneumonia, diphtheria, "grippe" and possibly dysentery were encountered as antecedent infections One of Dunn's own cases occurred during convalescence from appendicectomy, but the appendix was not acutely inflamed and there was no peritonitis. More recently McFarlane (1941) has described a case in which necrosis of the renal cortex followed multiple fractures and internal hæmorrhage, and in which a bacterial origin could be excluded

Relation to acute nephritis—Many of the infective conditions which have been associated with cortical necrosis are recognised causes of acute glomerulo-nephritis, and some of Dunn's cases appeared to be exceptionally severe manifestations of "war nephritis" As a result of his observations on the early glomerular lesions in acute nephritis (Dunn 1940) he and Montgomery suggest that the essential primary lesion, both in cortical necrosis and in acute nephritis, is a sudden dilatation of the glomerular capillaries, and that these cases of cortical necrosis should be regarded as examples of acute necrotising glomerulonephritis, the occurrence of ischæmic necrosis being determined by the severity of the lesion The finding of proliferative glomerulitis and epithelial crescent formation in some cases of cortical necrosis forms a link between this condition and glomerulonephritis Scriver and Oertal (1930) depicted crescent formation in one of their pregnancy cases, and Dunn found glomerulitis in a number of his non-pregnancy cases de Navasquez (1935) on the other hand, found no proliferative changes in his pregnancy cases, but described crescent formation in cortical necrosis produced by staphylococcal toxin The appearances described in the surviving tufts in our case might be regarded as evidence of slight proliferative glomerulitis

Role of shock and hæmorrhage—It has often been remarked that a retroplacental hæmorrhage precedes cortical necrosis of the kidney and it has been suggested that the sudden fall in blood-pressure is a factor contributing to renal ischæmia It is a question of interest whether shock, resulting from the perforation, operated in this way in our case Capillary stasis and hæmoconcentration, both features of shock, would contribute to arrest of the glomerular circulation The interval between the perforation and the first observation of renal symptoms might be regarded as evidence against this suggestion McFarlane's case already quoted, appears to be the only one in which shock and hæmorrhage alone have resulted in necrosis of the renal cortex

SUMMARY

In a man of 45 bilateral necrosis of the renal cortex followed perforation of a gastric ulcer

Recent observations suggest that glomerular capillary dilatation, leading to glomerular stasis, is the primary lesion in cortical necrosis Such dilatation may result from the action of bacterial toxins, and is regarded by some as the lesion common both to cortical necrosis and acute glomerulonephritis In pregnancy cases vasospasm probably precedes and determines capillary paralysis

In the case described bacterial toxins were probably responsible, but shock, with its resulting capillary stasis and hæmoconcentration, may have been a contributary cause

Prof J Shaw Dunn generously supplied us with material from one of his cases for purposes of comparison Our thanks are also due to Dr J P Steel, medical superintendent of Smithdown Road Hospital, for permission to publish this case, and to Mr R J Crompton, resident surgical officer at the hospital, for the use of his operation notes

BACTERIOLOGICAL AIR ANALYSIS BY THE CLOUD-CHAMBER METHOD

S D ELLIOTT, M D LOND , D P H
FREEDOM RESEARCH FELLOW, LONDON HOSPITAL

THE method to be described was developed in an attempt to evolve a means of bacteriological air sampling whereby the organisms would be isolated in a fluid rather than on a solid medium, as is the case with exposed plates and the air centrifuge [1] A preliminary report was made in April, 1941, to the epidemiological subcommittee of the Shelter Hygiene Committee of the Ministry of Health Further work had to be postponed, but the results obtained are published in the hope that others may follow up what appears to be a promising line of investigation

THE METHOD

The essential features are first, the trapping of suspended particles by drawing the air sample through a water-vapour mist, and second, the condensation of water on any particles left in suspension by cooling the saturated air The second principle is derived from that of the Wilson cloud chamber, in which the path of electrons may be observed by depositing on them water droplets condensed from a saturated atmosphere by a reduction in pressure

The air for analysis is drawn through a mist obtained by directing into a humidifying chamber a fine jet of steam, rapidly cooled by expansion to below 50° C In preliminary experiments the air was drawn through a large media funnel inverted over the spout of a bronchitis kettle which served as the source of water vapour Subsequently the funnel was replaced by a bulb shaped Pyrex glass flask of 5 litres capacity, air and mist being admitted through an opening 2 in in diameter in the bottom The lip of this opening was turned up into the flask about ½ in thus forming a channel in which the condensate forming on the inner wall of the chamber might collect A smaller opening resulted in too high a temperature being produced by the vapour in the flask The bronchitis kettle was later replaced by a flask of boiling water, part of the steam from which is directed through the opening into the humidifying chamber by a glass nozzle with an orifice 1 mm in diameter The steam passing through the nozzle is controlled by a screw clip on the rubber tube connecting it with the boiler In order to protect bacteria from direct contact with hot steam the nozzle should be screened by a conical shield of some poorly conducting material such as Cellophane In the experiments to be described this was not done The amount of steam passing through the nozzle must be controlled so that during air sampling the humidifying chamber is kept filled with a mist at a temperature not greater than 50° C without any excess vapour drifting back through the entry orifice

The upper part of the chamber tapers to an outlet ½ in in diameter through which the mixture of air and mist is withdrawn and passed through a condenser system the extent of which depends on the rate of air sampling In our experiments, two 10 in double surface condensers of the Liebig type connected in series were sufficient when air was sampled at the rate of 1/10 c ft per min The effect of setting the outlet to the chamber at the apex of a cone is to produce stream lining and even mixing of the air and water vapour as they are withdrawn

The outlet from the condenser system is connected with a suction pump through a flow meter of the manometer type and a cotton wool plug filter, which was introduced in order to test the degree of sterility achieved in the treatment of the air sample Where low rates of air flow are used the suction pump might be replaced by an aspirator bottle containing a known volume of water by whose displacement air can be drawn through the humidifying chamber and condenser system

RESULTS

The result of a single experiment is set out in the table A number of additional experiments were carried out along the same lines and with similar results

Ten c cm of an 18 hour broth culture of a readily identifiable serological type of salivary streptococci was sprayed into the upper air of a small room, 10 ft long, 5 ft wide and 10 ft high An ordinary De Vilbis throat spray was used, the atomisation produced being very coarse so that most of culture fell immediately to the ground, on which it duced a visible wet film A quarter of an hour ela between the end of spraying and the beginning of air sampling during this period the apparatus was assembled on a bench the room The humidifying chamber was then filled w mist and air drawn through at the rate of 1/10 c ft per m At the end of each of three 15 min periods air sampling w discontinued, the steam cut off, the condensate which h collected in the humidifying chamber flushed out with small quantity of sterile water and the cotton wool fi replaced by a fresh one These operations necessitated interval of 10 min between each 15 min period of air sampl Blood agar plates 4½ in in diameter were exposed for 15 m periods at the level of, and 12 in from, the entry to t humidifying chamber A fresh plate was exposed at t beginning of each period of air sampling At the end of t experiment the condensers and their connecting tubes we flushed out with sterile water and from each filter the cott wool plug was removed, teased out in 15 c cm of sterile br and then taken into separate flasks of glucose broth Th together with blood agar pour plates incorporating kno fractions of the chamber and condenser washings and the ent filter plug washings were incubated at 37° C for 48 hours

It will be seen from the table that there was a rap fall in the number of colonies on the successive plate exposed to the air of the room during the experiment This clearly shows the selectivity of the exposed plate in demonstrating large, rapidly falling, infected particle in the atmosphere At the end of an hour from the time of spraying, the blood-agar plate showed no strepto coccal colonies after 15 min exposure, whereas the cloud chamber still demonstrated a fairly high degree of atmospheric pollution

COMPARISON BETWEEN DEGREE OF AIR INFECTION DEMON STRATED BY THE CLOUD CHAMBER AND EXPOSED PLATE METHODS IN AN ARTIFICIALLY INFECTED ATMOSPHERE

1½ c ft of air sampled between	No of strep colonies from cloud-chamber washings	Cotton wool filter cultures *after passage* of air from cloud chamber (pour plates and glucose broth)	No of strep colonies on exposed plate
3 and 3 15 P.M	3000	Sterile	++
3 25 and 3 40 P M	450	,,	110
3 50 and 4 5 P M	150	,,	0

++ Too many colonies to count accurately (approx 2500)

Air spraying was begun at 2 40 P M and completed 2 45 P M

Air sampling was begun at 3 P M

The washings from the first and second condensers yielded 50 and 30 streptococcal colonies, respectively In addi to streptococci a few colonies of staphylococci and *Bacil subtilis* grew in each of the pour plates, except those made fr the filter plug washings which were sterile

DISCUSSION

Steaming is commonly employed for removing bacter and dust from the air inside hoods under which manipul tions requiring a high degree of sterility are sometim performed At one time this method of air sterilisatio was used in operating-theatres, but it has now b largely discontinued owing to the excessive humidit produced It has been observed that bacterial poll tion of the outside atmosphere is specially large at th level of the lower cloud limits (Flemming [2]), this ma part be due to the removal of bacteria from rising a currents by cloud formation

As a means of quantitative bacteriological air analy the method described here has certain limitations, b they do not seem insurmountable In our experimen only low rates of air sampling were used, and a dir relationship seems to exist between the necessar condenser space and the rate of air flow over it Furth the apparatus used in these experiments, althoug simple, is not easily transportable and does not len itself readily to use under crowded or difficult fiel conditions Time and facilities were not available for devising a more portable form of apparatus The id chamber has certain advantages over the other hods in common use Its efficiency in removing ptococci from the air appears to be high, judged by sterility of treated air as demonstrated by cotton-ol filters Theoretically, the efficiency does not depend olly on particle size, and it should be possible by this thod to isolate virus particles from the air Finally, organisms are recovered in a fluid medium , suitable ations can be put up for colony counts in selective dia as indicated by the probable degree of atmospheric lution and the particular organisms under investigation

My thanks are due to Mr T C Angus, D Sc , of the London hool of Hygiene, for the loan of an air pump and to Mr J D Wilson for technical assistance

GAS-GANGRENE OF THE EYE

Alexander G Cross, M.B Camb , F R C S
ATHOLOGIST TO THE ROYAL LONDON OPHTHALMIC HOSPITAL,
OPHTHALMIC SURGEON TO THE PRINCESS BEATRICE
HOSPITAL SQUADRON LEADER, R A F V R.

Gas-gangrene panophthalmitis is not common, ough cases have been reported by Chaillous (1904, 05), Darier (1905, 1906), Benedittı (1907), Schumaker 908), Oreste (1910), James (1910a and b) Lutz (1910) eath (1929), Ridley (1929) Hamilton (1930) Berry 932) and Walker (1934, 1938) There seems to be published record of any cases during the 1914–18 ar but details of one have been received in a personal mmunication from M H Whiting Consideration of e published reports and the following 12 cases which ve been treated during the past eleven years at the oyal London Ophthalmic Hospital enables the main atures of the infection to be described

TWELVE CASES

The patients were all male, ten being aged between 23 id 56, one aged 11 and one 64 All had received a erforating wound of the globe, and in seven of them is was associated with an intraocular foreign body other patients it was the result of injuries from such ticles as pieces of stick a stevedore's hook and the ner tube of a motor tyre In no case had the perfora-on been received more than 24 hours previously nophthalmitis was already present in six patients hen they were first seen, and the remainder developed e same condition within 24 hours of admission Severe in in the eye was a well-marked feature with brawny elling of the lids as in orbital cellulitis In two of the es bubbles of gas were seen in the anterior chamber eneral manifestations were slight, though some cases, here there was delay in removal of the eye, showed gns of toxæmia without much rise of temperature

The intraocular foreign body was removed from the ven patients where one was present, and in one recent jury a prolapse of the iris and ciliary body was abscised id a conjunctival flap stitched over the wound These easures had no effect on the progress of the condition, id removal of the infected eye was performed in every se, in eleven by evisceration and in one by enucleation en of the men were given anti-gas-gangrene serum ecovery was rapid and uneventful in all, the socket aling without complication, and where signs of xæmia were present these rapidly disappeared after e eye was removed *Clostridium welchii* was isolated om all the eyes, and, in addition, *Staphylococcus albus* om two of them The latter organism may be regarded contamination from the conjunctival sac

ÆTIOLOGY AND PATHOLOGY

A perforating wound of the globe, penetrating the treous, is the route of infection in all cases, and in any an intraocular foreign body is present No other naerobic organism has been found, but *Staph albus* was entified in two of my patients, and streptococci have peared in some reported cases The infecting organ-m has been thought to be present on the object causing e injury, but the variety of these and in some cases the parent lack of contamination with soil, manure or her recognised sources of *Cl welchii* suggests that the ganism may sometimes be present in the conjunctival c Benedittı (1907) has described a case of gas-ngrene panophthalmitis where *Cl welchii* had previously been isolated from a mucocele of the lacrimal sac, while Fava (quoted by Oreste 1910) has described the occurrence of the same organism on the lashes Males are affected almost exclusively, because of the greater likelihood of their receiving perforating wounds of the globe in their work In this series ten of the twelve patients fell within the usual age-limits of occupational diseases There is no evidence to show that hæmorrhage fatigue or a lowered general state of health bear any relation to the occurrence of the infection, nor does age seem to have any effect on incidence except by determining occupation

The enucleated eyes show the changes usually found in panophthalmitis The margins of the wound, anterior chamber, iris and ciliary body are densely infiltrated with polymorphonuclear leucocytes The lens is similarly affected when its capsule has been injured Many leucocytes are present in the vitreous and there is œdema, leucocytic infiltration, and destruction of the retina *Cl welchii* is present in the vitreous and inner layers of the retina and Chaillous (1905) has emphasised that they avoid the zone close to the choroid, which may be expected to have a relatively high oxygen content

CLINICAL MANIFESTATIONS AND TREATMENT

Acute panophthalmitis developing within 24 hours of a perforating injury of the globe and associated with severe pain is the characteristic clinical finding General collapse and pallor may follow if treatment is delayed A brown discharge from the wound may appear occasionally containing small bubbles of gas In the early stages an intraocular foreign body may be seen in the vitreous with a bubble of gas attached, and later gas appears in the anterior chamber

Evisceration of the globe without opening the subconjunctival tissues is the treatment of choice, but enucleation has been performed with equal success Anti-gas-gangrene serum has been given, but patients have recovered equally well when this has not been available Recovery has been rapid and uneventful in all cases, and of those described here all left hospital within two weeks of the removal of the globe In no reported case of gas-gangrene infection of the eye has the patient died from this cause There is no record of the effect of the sulphonamides in this condition

The course of gas-gangrene infection of the eye thus differs materially from that in other parts of the body ; this may be traced to anatomical peculiarities The factors which predispose to infection by gas-gangrene organisms are

1 Inadequate drainage of deep wounds
2 Presence of soluble calcium
3 Presence of foreign bodies, devitalised tissue and blood-clot
4 Impairment of circulation, as by tight bandaging
5 Involvement of muscle in the wounds

A perforating wound of the globe has no adequate drainage in many cases, and the vitreous, which is an inert substance without blood-vessels, contains soluble calcium For these reasons the globe is a potential site of gas-gangrene infection Elsewhere in the body the infection spreads in the tissue planes between muscle-fibres , lymphatic spread is slight, and invasion of the blood-stream is a late occurrence No muscle tissue connects the interior of the globe with another part of the body, and it has no true lymphatics The infection tends to remain localised until its severity becomes obvious, and eradication of this local infection prevents further spread

SUMMARY

Twelve cases of gas-gangrene panophthalmitis following a perforating wound of the globe are described Evisceration was performed in each case and recovery was rapid

The panophthalmitis develops within 24 hours of the injury and is accompanied by severe pain but little general disturbance

No deaths have been reported from this condition

I should like to thank the members of the surgical staff of the Royal London Ophthalmic Hospital for permission to publish these cases, and Dr S H Browning who carried out the bacteriological investigations

FORTY CASES TREATED AT THE ALLENDALE CURATIVE WORKSHOP

ELIZABETH CASSON, M D BRIST , D P M
MEDICAL DIRECTOR OF DORSET HOUSE SCHOOL OF OCCUPATIONAL THERAPY, CLIFTON

REHABILITATION needs serious attention at present An account of the first year of work at the Allendale Curative Workshop, opened at Clifton, Bristol, in 1939, is therefore of interest

The premises consisted of a former hotel with large ground-floor rooms and nearly an acre of garden Work had to be experimental, and each patient was made a special study Among the personnel was Miss Mary Macdonald, member of the Association of Occupational Therapists and head of the Dorset House School of Occupational Therapy She had then lately returned from a tour of orthopædic hospital occupational therapy departments in America having been given a research grant for this purpose by the Pilgrim Trust Dr Eugen Weissenberg, formerly in charge of the physiotherapy department at the university clinic, Vienna, joined us as a student Miss K Barber, another member of the A O T , and now in charge of occupational therapy at a Naval hospital, was also with us, and we had an enthusiastic teacher in Mr R C Cole, who was an excellent joiner Students of the Dorset House school engaged in their clinical practice with patients

Weaving and light crafts were carried on in a room which measured about 19 ft by 17 ft and allowed space for 10 patients Slightly heavier work, such as block printing and basket-making, was undertaken in a room (20 ft by 15 ft) which provided space for 9 patients More strenuous work, such as joinery and metal work, was carried on in a long room (42 ft by 15 ft) where benches, a lathe, and bicycle and treadle saws were provided , some embossing presses which had been given to us were also in this room The old dining-room (30 ft by 20 ft) was provided with a billiard table, and the conservatory gave room for darts

The first 40 cases show what useful work can be accomplished They came chiefly from fracture clinics at the hospitals, and were chosen by their surgeons because of some complication calling for special attention—joints fixed by adhesions, or bad habits of posture No patient was taken without prescription and full instructions from his doctor , in the case of patients from the fracture clinic, the occupational therapist in charge attended regularly at the clinic when the orthopædic surgeon was re-examining the patient, and heard his fresh instructions A report from the hospital almoner was also received on each case sent up Treatment was given in the mornings only, but the whole day should be occupied if possible before the patient is discharged back to work

CASE-HISTORIES

CASE 1 —A woman of 23 with arthrodesis of tuberculous hip After operation she had developed a functional disease of the knee joint She was lacking in self confidence and was too conscious of her disability Her inability to sit at an ordinary table seemed the chief cause of her unhappiness and also her inability to return to her work as a shorthand-typist She was taught to weave on a small loom with hand controls in order to interest her in the subject without referring to her leg She was then promoted to a foot power loom in which the warp was raised or lowered by flexing the knee joint While using the hand loom she had become so keen on the texture and pattern of the material she was weaving that was glad to perform the necessary movements, and was able to realise that her knee was quite capable of being to a more æsthetic posture Her gait improved at the time She asked to stay on for a few weeks to finish the leng material she was weaving and then returned to her office

CASE 2 —A man of 53, suffering from the after effec acute infective polyneuritis He had been completely p lysed for several months but had recovered sufficientl walk, and by several trick movements he could feed hi Treatment began with weaving a rug on a frame threaded w a warp of string The patient's deltoid and extensor mu were weak and could not bear the weight of his arms so th arms and hands were slung in canvas loops from brack extended from the top of the frame He had a spasm contraction of the shoulder muscles which relaxed when th arms were suspended Improvement became evident in t first few days, since the patient enjoyed the work The n stage was to support the wrists only on an adjustable s placed across the frame, again leaving the fingers fre weave and to push the threads into place, thus getting a extension of the fingers and wrists As the muscles imp in tone and strength, new crafts were prescribed, such knotting dog leads, stool seating and woodwork The d board for a few minutes each day helped in the cure

CASE 3 —A man, aged 61, who had had a compound fract of the radius from a conveyor belt accident His should had been strained, and he had arthritis of shoulder, elbow an wrist with much residual disability of shoulder, arm and for arm Mental depression was pronounced Treatment wa first given in the form of easy weaving on small hand loom at this time the therapist was making friends with the patient and gaining his confidence Later he made a warp on the "mill," encouraged by the knowledge that the warp wa needed for another patient's work An occupation had t be chosen that could be carried out at a level which gave eas abduction of the upper arm to begin with , this was increase gradually by raising the height of the mill without the patien noticing that he was doing more As soon as he realise that his angle of abduction had increased his confidence wa aroused and he then willingly cooperated in carrying o the changes in his work that increased the effort needed H recovery was completed by getting him to sand paper a paint screens raised to a level above his shoulder and to d holes in a solitaire board, which exercised flexion and ext sion of wrist Finally he did weaving on a large foot lo which enabled him to get larger movements , easy supinat was achieved by throwing and catching the shuttle

CASE 4 —A left handed man with compound fractur left proximal phalanx of ring finger and simple fractur little finger Even passive extension of these fingers w impossible Treatment was by joinery, which was his hobb first he did planing with fingers extended as far as possibl the plane, and then sawing and generalised movement, w various tools, to ensure complete movement and supple The patient was entirely cooperative and the fingers beca almost normal

DISCUSSION

These cases bring out the importance of the muscu spasm which often develops before treatment is beg Without occupational therapy this is difficult to ov come because the patient has allowed the wrong pos to become a habit Occupational therapy replace the patient's mind the image of a limb that he can use by one of a piece of work which that limb is acco plishing Much depends on the atmosphere into wh the new patient is introduced Allendale was essenti a happy place where people felt they would get w Each patient was welcomed and made to feel that h difficulties and disabilities were understood His pr tive impulses to investigate new surroundings, to s what he could perform, and to join in the activities of group, all had to be stimulated , and when the appropri emotion had been aroused the impulse was directed once into an activity that helped his recovery His f and suspicion had to be circumvented It usually t a few days to start a patient off well , many grasped t idea of what was intended in the first few minutes a became real enthusiasts in helping newcomers, but oth needed much care to begin with , but once they realis that a change had begun in the injured limb, th cooperation could be relied upon Special appara designed by Dr Weissenberg, was available to mea

angle of movement, and the patient could thus see a an actual graph what improvement he had made ;xperience has taught the following rules

The craft chosen must provide the exact muscle move-it needed at each stage It must be changed as the ent changes

The occupational therapist must superintend the move its continually, she must, therefore, have a complete nmg in anatomy and physiology, such as is required for ssage.

The patient's mind must be concentrated on the accom-hment of the work on which he is engaged Therefore it st be something that he enjoys doing and knows to be ful

The degree of strenuousness must be carefully regulated mature use of heavy tools can only do harm, and to itinue light work too long may produce a dilettante habit, l delay a man's return to his own work The equipment ist, therefore, include apparatus for heavy sawing and mmering Work should be increased until the patient is ing a full day's activity, which can include digging in the rden and pre-vocational work Games are a valuable junct A patient who thought he could not play billiards s seen to be acting as marker to the players, he walked ind and lifted his arm to mark, unconsciously exceeding at he believed to be his capacity -

Fear of infringing the rules of insurance companies d to be overcome Some patients thought that eatment might be counted as "work" and that it ould reduce their compensation, this doubt was best moved by the surgeon in charge of the case Only e man expressed fear of his trade union objecting, and ked "what the pay would be" for his work

The cost is important Only one of the first 40 cases as paid for by an insurance company Nearly all were ompensation cases and the money was just enough for e man to live on, most could not even afford their res to the curative workshop A small part of the cost as been covered by the Dorset House School of Occu-ational Therapy It is hoped that in time insurance ompanies will realise that occupational therapy lessens nd shortens disability and therefore reduces cost surance companies in America pay for such treatment nd even run their own rehabilitation centres for the jured workpeople whom they are compensating, ecause they know it pays them to do so Insurance ompanies in England already pay for medical treatment, ursing and massage, and might well make wise expendi-ure on this great aid to recovery

We have had to depend entirely on voluntary attend-nce, and it is difficult to ensure that the patient can be onvinced in the first or second visit that it is worth hile to persevere with treatment, perhaps at some onsiderable expense of energy and of money for fares hose who are intelligent enough to grasp at once the rinciple involved become enthusiastic quickly and help ewcomers to settle in But while numbers are small iose nearing recovery are few, and those who have covered have gone Definite instructions from the isurance companies paying compensation would help, this stage, to ensure regular attendance and conse-uent success

The injuries and disabilities treated included frac-ures of humerus, radius and ulna, wrist, metacarpals ialanges, scaphoid, os calcis and cervical spine, thritis, arthrodesis and ankylosis of joints associated ith such fractures, dislocation of the elbow, valgus formity of the feet, chronic strains, pareses of usculospinal, median, ulnar and circumflex nerves, rebral palsy, laceration of muscles and severed ndons after repair, limitation of movement after teomyelitis of the carpus, tuberculous osteitis of p and spine, acute infective polyneuritis, post-icephalitis, and traumatic neurosis Results are mmarised in the following table

At the beginning of the war arrangements were made r the workshop to undertake treatment under the M S, but enemy action having made it inadvisable r patients to remain in Bristol the workshop was trans-rred elsewhere Bristol patients are treated at Win-rd Hospital under Miss G E Barnes and Mr R C le in the wards and in a special occupational therapy it The Dorset House School of Occupational Therapy has now been transferred to Barnsley Hall Emergency Hospital, Bromsgrove, where it is fortunate in being under the direction of Dr Andrew Shepherd, the medical superintendent, who has paid special attention to occupational therapy in his hospital for many years Active rehabilitation work is again in progress there, and with the backing of the Ministry of Health will be on a much larger scale than was possible at Allendale

LENGTH OF TREATMENT AND ITS RESULTS IN 40 PATIENTS (32 MEN, 8 WOMEN) OF VARIOUS AGES

SUMMARY

A report is given on the first 40 cases treated at the Allendale Curative Workshop, attached to the Dorset House School of Occupational Therapy, Clifton, Bristol; 4 cases are described fully

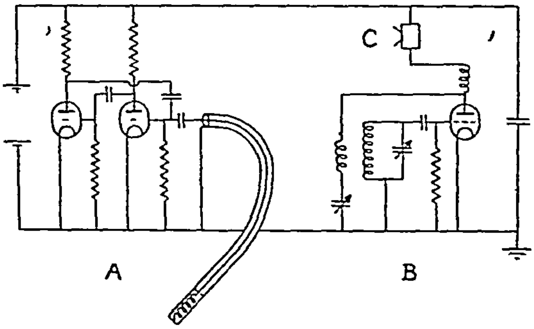
The cost of rehabilitating patients by occupational therapy might well be borne by insurance companies, as it is in America, this would allow of extension of this valuable form of treatment

I wish to thank Dr E Weissenberg and Miss E M Macdonald for their help in preparing this report, and to Dr H H Carleton, Mr K H Pridie, and Mr A L Eyre-Brook for allowing me to report on their cases

LOCATION OF FOREIGN BODIES BY A RADIO-FREQUENCY PROBE

F T FARMER, PH D CAMB S B OSBORN, B SC LOND
(*Barnato Joel Laboratories, The Middlesex Hospital*)

IN THE LANCET of May 31, 1941 (p 699), mention was made of an instrument, described in a broadcast from Germany, for locating metallic particles embedded in the body The device, which is intended to take the place of X rays in the operating-theatre, does not appear to have been used to any appreciable extent in this country



An experimental set has been assembled at this hospital The high-frequency oscillator (A in the diagram), working on a frequency of the order of 10^6 or 10^7 cycles per second, has the whole of its tuning inductance in the form of a search coil which can be moved about near the patient, and the second oscillator (B), working on a slightly different frequency, acts as a detector, and produces in the loudspeaker or telephone (C) a beat note equal to the difference between the two frequencies When the search coil comes near a piece of metal its inductance falls slightly, and the resulting frequency change is at once noticed in the note from the apparatus

The possible choice of radio-frequency is very wide the highest values give the greatest sensitivity to metallic bodies, but their practicability is limited by the stability of the apparatus and by the increasing effect of dielectric materials in the vicinity of the search coil relative to the effect of the metal itself A frequency of about 3×10^6 was found to be about the optimum Using this frequency, the apparatus will indicate the presence of a sixpenny piece at a distance of half an inch, and particles down to the size of a small pin closer to the search coil Larger bodies may be detected at slightly greater distances It does not seem possible to extend the effective range of an instrument working on this principle much beyond these values

The instrument is likely to be of value, in conjunction with X-ray examinations, for indicating the approximate position of metallic substances, in particular for assisting the surgeon while operating It cannot, it seems, be regarded as comparable in value with X-ray methods, by which the number and size of the particles are shown as well as their precise positions within the tissues

---

PULMONARY TUBERCULOSIS IN THE SERVICES

SURVEY OF 100 CASES

JOHN ASPIN, M B CAMB
RANDAL STALKER, M B EDIN
LATELY ASSISTANT MEDICAL OFFICERS AT A SANATORIUM

A SURVEY has been made of 100 soldiers and airmen suspected of having pulmonary tuberculosis who were sent directly to one sanatorium from military hospitals and sick posts The cases were admitted without selection in the order of application for beds Usually they came three or four weeks after the diagnosis had been made There were all types of soldiers, in all stages of the disease Some seemed comparatively healthy, some were evidently moribund We believe that this series of 100 consecutive admissions between June and December, 1940, is likely to be representative of the incidence of pulmonary tuberculosis in the Army and R A F at that time

Eight men were finally regarded as non-tuberculous, and were diagnosed as follows

Chronic bronchitis	2
Postpneumonic effusion	1
Postpneumonic fibrosis	1
Pleurisy (no tuberculous basis found)	1
Lung abscess	1
Effort syndrome	1
Congenital cystic disease of lung	1

The case of congenital cystic disease had received sanatorium treatment for tuberculosis at the age of seven After four weeks' military service (he had been a chef in civil life) he broke down with malaise, pleurisy and heavy staining Lipiodol bronchography performed at the sanatorium by Dr J W Seymour revealed that he was a typical case of generalised congenital cystic disease of the lung

RECRUITMENT OF KNOWN CASES

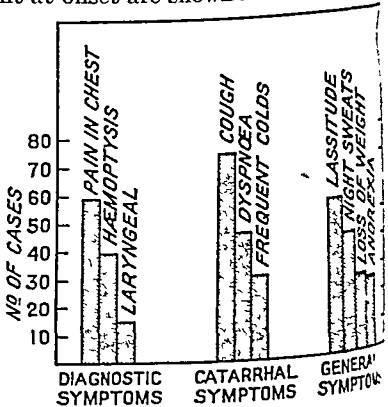
The series, which contains a proportion of men who enlisted before the Public Health (Tuberculosis) Regulations, 1940, came into force, includes 10 previously notified cases of tuberculosis, 6 of whom had been in sanatoria There were 4 men considered to have active pulmonary lesions at enlistment, one of these, who had previously refused institutional treatment, was invalided after his tuberculosis officer had communicated with the military authorities An arrested case whose history has been published (Aspin 1940) had been discharged from the Army in February, 1940, after a breakdown Before June in the same year not only had he contrived to re-enlist in another regiment but he had broken down and had been invalided for a second time At the time of enlistment 3 other men had quiescent pulmonary lesions, while 2 who were previously non-pulmonary cases broke down in the Service with pulmonary lesions

Most of these men had concealed some essential of their history when they came before medical bo and one or two had deliberately made false statemen Although one man admitted that he had joined up t get a "soft job," and revealed a previous history of san torium treatment when he found himself on the parad ground, the others gave us the impression that they f they were helping their country when they enl Under the Public Health (Tuberculosis) Regulation 1940, the medical boards who examine recruits are n made acquainted, as far as possible, with the previ history of examinees whose names are on the tuberculo registers In addition, the Ministry of Labour now a every examinee before a medical board to sign a decla tion that he has not at any time suffered from tuber losis In this way the future recruitment of know cases of tuberculosis should largely be avoided T need for such measures is shown in a series published Kersley (1941) who, in the first 100 men that he examin and boarded out of the Army, found clear evidence t 18 had been in sanatoria and that 15 more had b suffering from the disease before enlistment

MODE OF ONSET

In about two-thirds of our cases the onset was gradu Several symptoms had usually appeared before t soldier reported sick In the remainder the onset w more abrupt and indeed often dramatic, 9 men reported sick after a considerable hæmoptysis, which in 6 had happened while on duty One man was digging in a deep trench when suddenly he developed a spontaneous pneumothorax There were 18 cases of pleurisy with effusion in which sudden severe pain was the presenting symptom Of these men, 10 were well and gave no symptoms or signs of chest trouble until the day the pain began In these 10 cases fluid was demonstrated 4–25 days after the onset of the pain

Examination of the symptoms present when the men reported sick showed that there were only 20 cases in which there had not been pain in the chest, hæmopty or staining, 59 men said they had pain in the ches 39 had coughed up blood or blood-stained sputum, T reported both pain in the chest and hæmoptysis Th symptoms present at onset are shown in the figure



Frequency of initial symptoms

In 7 cases the diagnosis was made while they were under investigation in hospital for apparently unconnected conditions—hernia, error of refraction, gastritis, mastoid infection, wounds, dysentery and acute encephalomyelitis, 2 men complaining primarily of hoarseness were diagnosed as tuberculous by ear, nose and throat specialists to whom they w referred

A history of considerable distress during phy training was given by 24 men, of these, 14 had to harder physical work since joining up Of the 76 m who felt no undue distress during physical training had to do harder physical work While the dis was more advanced in cases showing distress dur physical training, previous occupation seemed influence the degree of dyspnœa experienced It evident that a labourer would not complain of breath lessness after exertion that might be troublesome to sedentary worker

NATURE OF LESIONS AND STAGE OF DISEASE

Obviously abnormal physical signs in the chest w present in 48 cases and clubbing of the finger-nails in

In 46 men the lesions were unilateral, while 53 show bilateral disease Cavitation was present in 40 c ding 14 in which one lung was only involved e were 18 cases with pleural effusion, in 11 of which rlying shadowing was visible, 1 of the simple ions was regarded as non-tuberculous Definite ; of fibrosis, as shown by displacement of the heart achea, or thickening of interlobar septa, were found ie radiograms of 14 cases, while 20 more showed less ous evidence of contracting lesions In 13 cases e was definite calcification, and in 8 of these the ified areas were well outside the hilar regions

Vhen the original diagnosis had been confirmed, 92 s remained These were arranged according to the sification of the Ministry of Health into class TB us (sputum negative or absent), class TB plus itum positive) groups I, II and III (early, moderate advanced cases) The proportions were found to TB minus 35 9%, TB plus group I, 11 9%, up II, 41 3%, and group III, 10 9% To compare se figures with those from an area with a highly de- oped tuberculosis scheme, the numbers of new patients h pulmonary disease applying for treatment during 6, 1937 and 1938 were obtained from Dr G Lissant x, central tuberculosis officer for Lancashire The nen, who were actually on the register at the time enlistment, were removed from the series of Service ses, and the 83 remaining new cases compared with new cases applying for treatment under the Lanca- re scheme

BLE I—STAGE OF DISEASE IN SERVICE CASES AND IN NEW CASES APPLYING FOR TREATMENT IN LANCASHIRE

Stage	No of cases		Percentage	
	Lancashire	Service	Lancashire	Service
minus	1209	33	35 5	39 8
plus group I	271	8	8	9 6
group II	1473	33	43 3	39 8
group III	451	9	13 2	10 8
Totals	3404	83	100	100

These two sets of figures show considerable similarity casual inspection might suggest that the Service cases ere slightly less advanced, but in such a small series e differences might easily be expected as a sampling ror It is concluded that in these soldiers and airmen pul- onary tuberculosis was diagnosed while the disease was more advanced than it would have been in new cases plying for treatment under the Lancashire scheme

PAST HISTORY AND DURATION OF SERVICE

Kayne (1940), in a survey of 134 cases, found that the ain criteria adopted by medical boards in selecting ses for special examination were statements of berculosis in the family, "pleurisy" in the past, or lmission to a sanatorium or attendance at a tuberculosis inic in childhood or adolescence Since in his series he und only 2 men with active tuberculosis and 1 with cently active tuberculosis, Kayne concluded that stories of tuberculosis in family and pleurisy in the st as given by the recruit cannot be relied on to detect ore than a small fraction of recruits with either active healed pulmonary lesions

In the present series 18 out of 92 cases of tuberculosis ive a history of a parent, brother or sister either being eated for pulmonary tuberculosis or dying with the sease, 5 of these cases and 10 others gave a history of emoptysis or pain in the chest with pyrexia before listment These figures suggest that in Kayne's ries the lack of positive findings may have been due to reliable statements and the concealment of relevant cts by the recruits themselves This unreliability has en confirmed in our series by the enlistment of known ses of tuberculosis Others who wished to be dis- arged from the Army because they had been worried out their health freely confessed that they had made false atements, or had withheld essential information, when ey were examined by the medical recruitment board

Three-quarters of these men were conscripts whose ilitary service amounted to less than a year Indivi- al service, however, varied over a wide range A M S had been 24 years with the colours An "AC2" d 5 days' service to his credit While 4 old regulars could muster 64 years' service among them, 12 others could not together make up six months' service (table II)

TABLE II—DURATION OF SERVICE

—	Less than 1 month	1–3 months	3–6 months	6–12 months	1–2 years	More than 2 years
No of cases	16	18	19	23	14	10

DISCUSSION

Tuberculosis among men who served in the last war gave rise to serious problems even in the postwar years, and pensions for tuberculosis accepted by the state as "directly attributable to, or seriously aggravated by" military service continued to be given for many years after the war was over Mitchell and Smith (1931a) state that 65,370 such pensions were awarded up to March, 1929, representing 7 6% of the total pensioned disabilities up to that time Positive sputum was then the chief criterion for the diagnosis of pulmonary tuberculosis (Joint Tuberculosis Council Report 1939) Although the wastage in man-power from tuberculosis during the last war was negligible (Mitchell and Smith 1931b), many men suffering from pulmonary tuberculosis were returned to duty, with a consequent risk of infecting their comrades. Thus, from 1916 onwards 21% of the cases arising in the British Army were returned to duty (Mitchell and Smith 1931c)

The problems presented in this war by tuberculosis arising in the armed forces seem likely to be less acute The death-rate from pulmonary tuberculosis has fallen steadily, and is now less than half what it was in 1918 Enlistment of known cases of tuberculosis, so common in the early stages of the last war, will be largely prevented by the new regulations The risk of contact infection is further diminished because men diagnosed as tuberculous are now returned to duty only in exceptional circumstances All examinees before medical boards suspected of being tuberculous are at once referred to the tuberculosis officers for special examination Our figures show that in one small series at least tuberculosis arising in soldiers and airmen was diagnosed as soon as it would have been among civilians and that more than a third of these men were negative cases Cases discovered in the Services are sent to special hospitals where full treatment is started at once, and when they are discharged from the Services, this treatment is continued by their local authority At least one tuberculosis colony, the Papworth Village Settlement, is already offering the benefits of colonisation to suitable cases invalided from the Services

These real advances are not enough to prevent the recruitment of men likely to break down with active pulmonary tuberculosis within a few months of joining the Services In our series, out of 92 men, active lesions had been found within three months of enlistment in 29 cases (31 5%) and within six months in 48 cases (52%) These figures are less disturbing if it is remembered that mass radiography, whenever it has been performed on symptom-free people, has revealed active tuberculous lesions in 0 5–5% of them Heaf (1940) has discussed the value of mass radiography in peace-time in combating the spread of infection by revealing the hidden active cases among the apparently healthy population Even when men have previously been examined clinically, mass radiography has demonstrated some, though fewer, unsuspected active lesions Berner (1939) in 10,852 picked storm-troopers who had been screened found 0 8% of such cases Among 9000 recruits from the Australian Imperial Forces, Cooper (1939) discovered 0 55% of active cases, and Galbraith (1941), in a later report, states that out of more than 100,000 such recruits 0 56% showed radiological evidence of active pulmonary tuberculosis Sheldon Dudley (1941), reporting the results of mass radiography in the Royal Navy, where screen-photography is now performed as a routine, found an incidence of 0 32% active cases of pulmonary tuberculosis in 11,000 new entrants

Kayne (1940) holds that without routine radiological examination the detection of unsuspected pulmonary tuberculosis in recruits is impossible If the administrative and technical problems be overcome, there seems to be a strong case for the extension to the Army and

R A F of mass radiography by screen-photography using 35 mm cinema film The position has been ably summarised by Bentley and Leitner (1940) —

> "It is not suggested that screen photography will abolish tuberculosis from the Services, but it would eliminate a sensible proportion of tuberculous subjects who should not be allowed to serve It is thought the saving in pensions alone would more than outweigh the cost of the investigation "

Probably many men in our series were unsuspected cases of tuberculosis when they joined up, and we have tried to find out how many would have shown radiological lesions visible by miniature radiography at the time of enlistment

No-one would deny the difficulty, and some would question the possibility, of estimating the radiological appearances some time before a radiogram was taken We were guided by duration of service, extent and density of the lesions, presence of cavitation, and clinical course of the disease When a man had served for longer than six months, especial attention was given to definite signs of a contracting lesion, presence of hard shadowing or calcification in the lung fields, and previous history suggestive of tuberculosis The cases have accordingly been divided into two groups—those in which miniature radiography at enlistment would, in our opinion, have revealed lesions suggestive of pulmonary tuberculosis, and others in which miniature radiography would have given no help (table III)

TABLE III—SERVICE CASES IN WHICH MINIATURE RADIOGRAPHY AT ENLISTMENT WOULD PROBABLY HAVE REVEALED LESIONS SUGGESTIVE OF TUBERCULOSIS

Period of service (in months)	No of cases	Estimated result of M R	
		No help	Suggestive lesions
Less than 1	16	5	11
1– 3	18	5	13
3– 6	19	7	12
6–12	23	15	8
12–15	11	9	2
More than 15	13	13	0
Total	100	54	46

We estimated that in 46 cases abnormal shadowing or displacement of the mediastinum would have been clear enough at enlistment to have been detected by miniature radiography, though careful physical examination and history-taking had revealed no evidence of tuberculosis

SUMMARY

A survey has been made of 100 Service men suspected of having pulmonary tuberculosis The stage at which the disease was diagnosed in these men did not differ materially from the stage at which cases are diagnosed in civil life

Reasons are given for the belief that in this war spread of disease by infection in the Services is likely to lead to fewer cases of pulmonary tuberculosis than in 1914–18

In this series active pulmonary tuberculosis was found within three months of enlistment in 29 cases, and within six months in 48 cases

Miniature radiography at enlistment would probably have revealed definite lesions in 46 of our cases

We wish to thank Dr J W Seymour, late acting medical director of the sanatorium, for permission to report these cases and for advice, Dr G Lissant Cox, who allowed us to quote figures from his annual reports, and Dr George Jessel, who first suggested this survey

ANTERIOR DISLOCATION OF RADIAL WITH FRACTURE OF SHAFT OF ULNA

E N- WARDLE, M CH LPOOL, F R C S
ASSISTANT ORTHOPÆDIC SURGEON TO THE ROYAL SOUTHERN HOSPITAL, LIVERPOOL, ORTHOPÆDIC SURGEON TO THE BIRKENHEAD GENERAL HOSPITAL

IT cannot be said that anterior dislocation of the h of the radius with fracture of the shaft of the ulna suffered in the past from lack of attention or inve tion The lesion is relatively rare, but recorded c show that it has attracted notice since the beginning the last century, when it was first described by Monte who recognised it without the aid of X rays I reco here 4 new cases illustrating the successive poin emphasised by various authors during the last ten ye

It has been taught for some time that where there i fracture of the shaft of the ulna with displacement th elbow-joint should always be included in the radiogra because shortening of the ulna necessarily means th disruption of one or the other radio ulnar joints, usuall the superior one (Campbell 1929, Corbett 1931, Wilk 1933) Cases 2 and 3, reported here, however, showed subluxation of the head of the radius with only an incom plete fracture of the shaft of the ulna, unaccompanied by any displacement, so that it seems important always to examine the elbow-joint both with the finger and by means of X rays

Several writers have paid great attention to the exact mechanism causing the injury, but it seems to me more important to recognise that this dislocation of the radial head can only take place as a result of disruption of the orbicular ligament Hunt (1939) and Campbell (1929) both describe this ligamentous tear, as do several later observers, but the standard textbooks of fracture (e g Scudder 1926, Sinclair 1931) made no mention of it until it was referred to by Kellogg Speed (1935) and Bohler (1935) Wilson (1938) gave a complete descrip tion of the pathology My own observations have con firmed the ligamentous tearing in each case, and I hav particularly noted that the torn ends were alw retracted deep to the radial head and that, at the ulna attachment, the ligamentous strands were so short torn as to be useless for reconstruction

CASE-HISTORIES

CASE 1 —Age 13 Fell on the right elbow in Novem 1938 X ray report of forward and outward dislocati the head of the radius and fracture of the ulna The c location was replaced manually, but the reduction was stable At open operation on Dec 6 the ordinary exte lateral approach to the head of the radius was used, but it w difficult to reach the front and inner side of the head The torn edges of the orbicular ligament were demonstrated and an attempt made to suture them The radial head dislocated for the second time a few weeks later, but despite the deformity the functional result was good and by April, 1939, there was full range of elbow movement and the

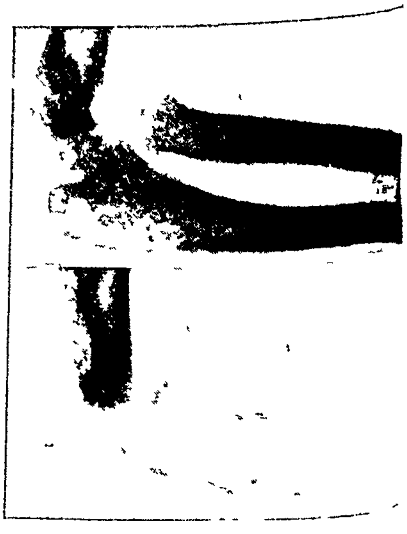

FIG 3—Case 4 (*a*) Lateral view of elbow sho dislocation of head of radius (*b*) Lateral of elbow showing stable reduction of disl radial head after reconstruction of orbi ligament

at appeared to se the patient trouble

ASE 2 —Age Accident on g 8, 1939 diography revealed an anterior location of the ad of the radius companied by incomplete acture of the na without any splacement gain the head of e radius was sily replaced manual reaction under aæsthesia, but in case 1 the islocation curred readily t operation on ug 16 an anterior incision at e outer side of e antecubital ssa was used, was particularly noted that ccess to the ead and neck of e radius was uch easier and as obtained by etracting supinator longus outwards and brachialis anticus wards In this case also the torn ends of the orbicular gament were found curled up deep to the radial head, but even ith the better approach attempts at suturing the ligamentous emains were unsuccessful X rays showed that the islocation recurred

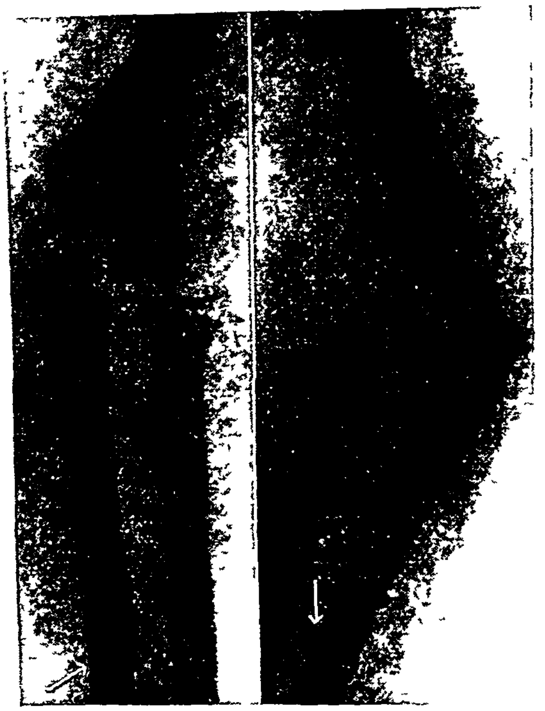

FIG 1—Case 3 Anterior and lateral views of elbow showing dislocation of head of radius and fracture of shaft of ulna Arrows in figs 1, 2, 3 indicate site of fracture of ulna

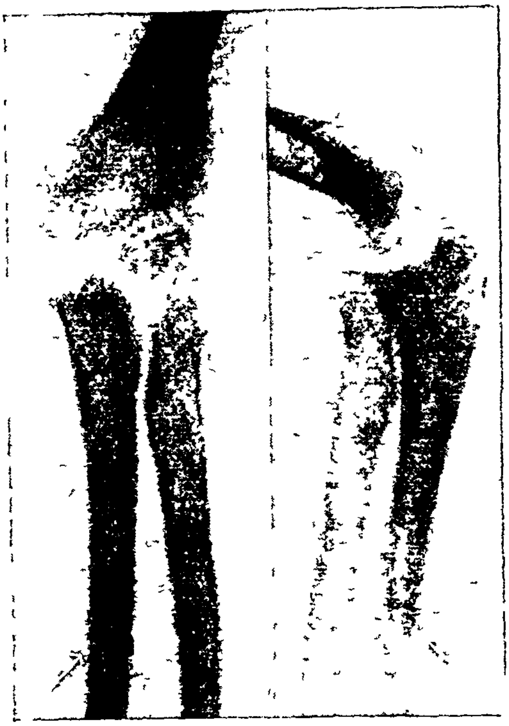

FIG 2—Case 3 Anterior and lateral views of elbow after reconstruction of orbicular ligament

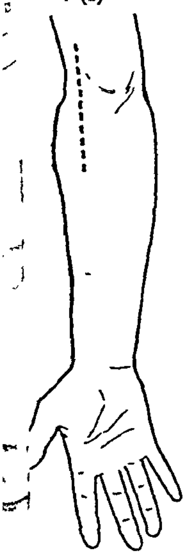
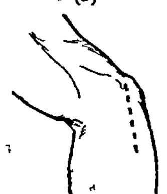
CASE 3 —Age 7 Fell on the right arm in June, 1940, and stained a fracture of the middle of the shaft of the ulna, ith anterior dislocation of the head of the radius (fig 1) t operation on June 18 the anterior approach was used and e torn orbicular ligament was easily demonstrated The peration described below was carried out The elbow was imobilised for 4 weeks and then active movement was allowed fter 4 months the patient had a full range of movement, and X rays showed that reduction of the dislocation was stable (fig 2)

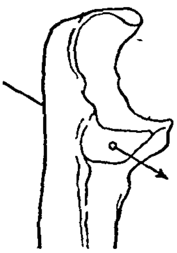
4 (a)



4 (b)



6



g 4—Right arm (a) Anterior cubital incision (b) Incision on inner side of elbow parallel to posterior border of ulna

G 6—Head of ulna showing bore hole

CASE 4 —Age 14 Accident on July 31, 1940 Dislocation of the head of the radius Manual reduction was easy but dislocation of the radial head recurred in plaster (fig 3a) Operation as in case 3 was carried out After 3 weeks' immobilisation the plaster was discarded and a month after that the child had a full range in the elbow and the joint has remained normal since Fig 3b illustrates the stability of the reconstructed orbicular ligament

OPERATION

The anterior incision (fig 4a), used in the cases I have described here, was made to the outer side of the antecubital fossa, according to the directions given by Campbell, Corbett and Wilson In the upper part of the incision the gap between supinator longus on the outer side and brachialis anticus and biceps on the inner side was defined, and these muscles were retracted, the posterior interosseus nerve going with supinator longus This line of cleavage was carried downwards so that the head of the radius and the inner and upper border of supinator brevis came into view Small deep retractors were then inserted and the head and neck of the radius, with the torn ends of the orbicular ligament, were defined (fig 5) A second incision was then made at the inner side of the elbow parallel with the posterior border of the ulna (fig 4b) The ulnar nerve was defined as it comes out of the postcondylar groove and retracted posteriorly, so that the inner surface of the olecranon was available At the level of the superior radio-ulnar joint a drill hole was then made through the base of the olecranon process, emerging at the lesser sigmoid cavity of the ulna (fig 6) A loop of kangaroo tendon was then passed around the neck of the radius and both ends threaded through the eye of an aneurysm needle which was passed along the drill channel in the ulna to emerge in the superior radio-ulnar joint The two ends of kangaroo tendon were then brought out at the inner surface of the ulna and knotted in

E N WARDLE, M CH LPOOL, F R C S
ASSISTANT ORTHOPÆDIC SURGEON TO THE ROYAL SOUTHERN HOSPITAL, LIVERPOOL, ORTHOPÆDIC SURGEON TO THE BIRKENHEAD GENERAL HOSPITAL

IT cannot be said that anterior dislocation of the h of the radius with fracture of the shaft of the ulna suffered in the past from lack of attention or inves tion The lesion is relatively rare, but recorded c show that it has attracted notice since the beginning the last century, when it was first described by Monte who recognised it without the aid of X rays I rec here 4 new cases illustrating the successive poi emphasised by various authors during the last ten yea

It has been taught for some time that where there fracture of the shaft of the ulna with displacement t elbow-joint should always be included in the radiogram because shortening of the ulna necessarily means t disruption of one or the other radio ulnar joints, usu the superior one (Campbell 1929, Corbett 1931, Wil 1933) Cases 2 and 3, reported here, however, show subluxation of the head of the radius with only an inco plete fracture of the shaft of the ulna, unaccompanied by any displacement, so that it seems important always to examine the elbow-joint both with the finger and by means of X rays

Several writers have paid great attention to the exact mechanism causing the injury, but it seems to me more important to recognise that this dislocation of the radial head can only take place as a result of disruption of the orbicular ligament Hunt (1939) and Campbell (1929) both describe this ligamentous tear, as do several later observers, but the standard textbooks of fracture (e g Scudder 1926, Sinclair 1931) made no mention of it until it was referred to by Kellogg Speed (1935) an Bohler (1935) Wilson (1938) gave a complete descrip tion of the pathology My own observations have co firmed the ligamentous tearing in each case, and I ha particularly noted that the torn ends were alwa retracted deep to the radial head and that, at the ul attachment, the ligamentous strands were so short torn as to be useless for reconstruction

CASE-HISTORIES

CASE 1—Age 13 Fell on the right elbow in Nove 1938 X ray report of forward and outward dislocati the head of the radius and fracture of the ulna The location was replaced manually, but the reduction was stable At open operation on Dec 6 the ordinary exte lateral approach to the head of the radius was used, but it difficult to reach the front and inner side of the head The torn edges of the orbicular ligament were demonstrated and an attempt made to suture them The radial head dislocated for the second time a few weeks later, but despite the deformity the functional result was good and by April, 1939, there was full range of elbow movement and the

onchogenic origin, who were treated with sulphathiazole

CASE-REPORTS

CASE 1 —Man of 59 Pneumonia complicated by lung bscesses and empyema Admitted Feb 2, 1941, on 4th ay of disease, very ill with high fever, dyspnœa and cyanosis onsolidation in upper- and mid zones left lung From 4th o 14th day sulphapyridine, 55 g , given by mouth Pyrexia ess for 2 days only Consolidation developed in right midone Between 14th and 17th day pyrexia continued and adiography revealed cavity in left mid zone Sputum 8–12 oz daily) showed predominating growth of *Staph ureus* as well as some *Streptococcus hæmolyticus* From 17th o 23rd day sulphathiazole, 36 g , given by mouth , apyrexial after 48 hours and showing much clinical improvement Right lung cleared satisfactorily, but abscess persisted in eft lung From 28th to 30th day there was further pyrexia educed by sulphathiazole Aspiration of sterile, turbid, erous effusion from left pleural cavity carried out on 43rd nd 49th days On 61st day recurrence of pyrexia with acute nephritis Left pleural effusion now found to give good rowth of *Staph aureus* and moderate growth of *Strep hæmolyticus* Blood urea, 47 mg per 100 c cm After another course of sulphathiazole, patient became apyrexial after 3 days and nephritis cleared up after 5 days Empyema persisted and intercostal drainage instituted on 66th day Sulphathiazole concentration in pleural fluid was 8 6 mg per 100 c cm and in blood 15 5 mg per 100 c cm Although dyspnœa and tachycardia improved considerably, empyema cavity remained large and on 94th day rib resection was done under local anæsthesia and drainage begun Patient then made a good recovery, empyema cavity closing in and lung abscess no longer being visible radiologically

CASE 2 —Woman of 62 Staphylococcal pneumonia Admitted Jan 31, 1941, on 7th day of illness Toxic, with consolidation of left lower lobe From 7th to 15th day sulphapyridine, 48 g , given by mouth Temperature fell slightly at first but soon rose to higher than before and lung signs persisted Copious purulent sputum gave good growth of *Staph aureus* From 15th to 22nd day sulphathiazole, 80 g , given by mouth Apyrexial after 4 days , fever recurred on 21st day and 2 oz of sterile turbid fluid aspirated from left pleural cavity Permanently apyrexial after 23rd day and lung condition cleared satisfactorily Radiogram of chest showed no lung abscess

CASE 3 —Girl of 16 Staphylococcal empyema probably complicating influenzal pneumonia Admitted Jan 28, 1941, on 6th day of illness, very ill, pale and toxic with palpable spleen Signs of right basal pneumonia with pleural effusion From 6th to 12th day sulphapyridine, 36 g , given by mouth Further rise in temperature On 8th day aspiration of sterile serous effusion from right pleural cavity No tubercle bacilli in sputum X rays showed opacity right base with doubtful evidence of lung abscess and loculated pleural fluid On 13th day more turbid fluid aspirated , this grew *Staph aureus* From 16th to 20th day sulphathiazole, 36 g , given by mouth , no improvement Pyrexia continued and was unaffected by further aspirations of the empyema, in which *Staph aureus* persisted Sputum showed no staphylococci, but was not examined for these organisms until 18th day On 21st day rib resection was done and drainage instituted Biopsy of pleura showed no evidence of tuberculosis Gradual improvement followed, patient becoming apyrexial and sinus healing

CASE 4 —Man of 18 Boil on chin with sterile empyema Admitted Feb 7, 1941 Boil for 6 days and left pleuritic pain for 3 days On admission febrile and toxic Large furuncle on chin and left pleural effusion, which on aspiration was found to be purulent but sterile on culture Blood-culture sterile X rays showed opacity at base of left lung From 6th to 12th day sulphathiazole, 40 g , given intravenously plus 48 g by mouth Further aspirations of pleural fluid on 7th and 8th days showed effusion to be less purulent and still sterile Sulphathiazole content of pleural fluid 8 9 mg per 100 c cm Drug rash appeared on 12th day Patient became permanently apyrexial on 13th day, by which time furuncle and lung condition had almost cleared up *Staph aureus* cultured from furuncle

SUMMARY

A group of 4 patients (2 male and 2 female) with staphylococcal pulmonary infections were treated with sulphathiazole , 3 of them had failed to respond to sulphapyridine

All recovered, though 2 required drainage of empyemas

I wish to thank Dr W Allen Daley, medical officer of health to the London County Council, for permission to treat these cases The sulphathiazole used in the clinical trials was supplied by Messrs May and Baker Ltd

ACUTE LARYNGITIS COMPLICATED BY RECURRENS PARALYSIS

A J MOFFETT, M B BIRM , F R C S
MAJOR, R A M C , ASSISTANT SURGEON TO THE EAR AND THROAT HOSPITAL, BIRMINGHAM

THE two cases here recorded, both in soldiers were seen within a few days of each other during a period when acute upper respiratory infections were fairly common

CASE 1 —Age 19 Ten weeks before examination had a severe sore throat, followed in a few days by gradual loss of voice When seen could speak only in a whisper but could make a loud harsh noise when coughing Throat, nose and pharynx mildly congested Both antra dim on transillumination, but right antrum washout showed no macroscopic pus Subacute inflammation of larynx with little muco pus on right vocal cord Trachea shared in general inflammation Right vocal cord showed complete recurrent paralysis, cord being in cadaveric position Right arytenoid could be moved with a probe

X ray appearances of chest normal No glands palpable in neck Postnasal swab gave Freidlander's bacillus and pneumococcus on culture , no diphtheria bacilli

Three days later voice returned gradually, but it had peculiar cracked sound which patient stated was not there prior to illness Two weeks later voice and appearance of vocal cords, except for gradual subsidence of inflammation, were unchanged

CASE 2 —Age 38 Twelve days before examination was walking to duty on a bright but cold frosty morning Had gone only short distance when became aware of slight tickling in throat This got steadily worse from day to day, until two nights before examination was awakened from sleep by violent fit of coughing Had several severe paroxysms ending in alarming inspiratory stridor which made him hold on to the bed to get his breath Paroxysms recurred nightly, most severe being on night before examination No loss of voice Looked ill T 99° F , P 100 per min Nose and pharynx acutely inflamed , pharynx studded with œdematous lymphoid follicles and very sensitive Small tender gland on left side of neck at level of hyoid bone Larynx acutely inflamed , vocal cords and mucous membrane bright red Trachea also inflamed Left vocal cord showed paralysis in which some adductor movement was still present Arytenoid mobile That night had another slight paroxysm of coughing, but improved rapidly with expectorants, inhalations and rest in bed X-ray appearances of chest normal Postnasal swab gave few *Staphylococcus aureus*

Ten days later condition had improved considerably Paralysis of left cord now complete but laryngitis less inflamed Voice tired easily and had not improved after a further ten days sick leave Ten weeks after onset laryngitis had disappeared and paralysed cord had regained considerable range of movement

The distressing inspiratory stridor experienced was probably due to an abductor paralysis in the early stages

IN " The Battle of Britain " (Puffin Picture Book 6d) David Garnett has retold the story of August–October 1940 and James Gardner has illustrated it in colour The Air Ministry account, on which this is based, must have thrilled every grown person in the country , this will bring in the under-sixteens such a way as to prevent any sliding back As this manœuvre was carried out the head of the radius could be seen to reduce into both elbow and superior radio-ulnar joints and the stability of the reduction could be demonstrated before the wound was closed Both incisions were closed and the arm fixed in plaster

If the importance of the torn orbicular ligament is admitted, rational treatment will obviously aim at its reconstruction It is remarkable that although Campbell (1929) advised and carried out the procedure here described, books on fractures show a division of opinion about what should be done Bohler (1935) says that the dislocation is reduced by traction on the forearm with pressure on the head of the radius, and that if this is done early the orbicular ligament will heal and perfect function be restored Kellogg Speed (1935) notes that reduction is difficult and mentions restoration of the orbicular ligament by a fascial graft passed through a hole drilled in the ulna Watson-Jones (1940) recommends reduction as described in Bohler's textbook but advises reconstruction of the orbicular ligament in late cases where the fracture of the ulna is malunited or non-united Wilson (1938) emphasises that in all cases there is a rupture of the orbicular ligament and states that while dislocation is easily reduced by closed manipulation it is impossible to retain the position He recommends reconstruction of the orbicular ligament by a fascial sling passed through the ulna

In my experience, though it is easy to replace the radial head by closed manipulation, the displacement always recurs The reason seems to be the curling up of the ligamentous ends beneath the radial head , in addition the orbicular ligament is usually so much damaged as to make primary repair impossible It is also evident that the degree of pressure which has necessarily to be kept on the head of the radius while the elbow is fixed in plaster is not safe Even those surgeons who agree that reconstruction of the orbicular ligament is the only sound method of obtaining success in these cases, differ considerably about the way to achieve it Hunt's suggestion (1939) of simple suture of the torn ends seems to be a counsel of perfection rarely possible to follow The same objection holds for Corbett's method of plastic repair with a strip of bicipital fascia , there is not enough of the torn orbicular ligament left, particularly in a small child, for adequate fixation of the repairing strip Campbell, Wilson and Kellogg Speed all carry out their reconstruction by drilling a hole through the upper end of the ulna The results in my cases 3 and 4 illustrate the success of this method, and it is probably of little importance what material is used for constructing the new orbicular ligament

SUMMARY

Four cases of anterior dislocation of the head of the radius, associated with fracture of the shaft of the ulna, are reported

The best method of treatment seems to be open reduction of the dislocated radial head through an anterior incision, with reconstruction of the orbicular ligament by means of a loop passing round the neck of the radius and secured through a hole drilled in the upper end of the ulna

SULPHATHIAZOLE IN STAPHYLOCO LUNG INFECTIONS

GEORGE MELTON, M D LOND , M R C P
SENIOR RESIDENT PHYSICIAN AT LEWISHAM HOSPITAL, L C C

STAPHYLOCOCCAL infection of the lungs is well rec nised as a complication of staphylococcal septicæmia a pyæmia Staphylococcal pneumonia may however ha a bronchogenic origin and such cases have particular been observed during influenzal epidemics (Chicker and Park 1919) In influenzal patients the staphy coccus plays the part of a secondary invader, either al or in combination with other organisms Apart fr these epidemics, staphylococcal pneumonia does n appear to be common, though occasional reports of t occurrence, particularly in children but also in adu have been published (Reimann 1933, Macgregor, 19 Everley Jones 1938, Kanof et al 1939) It is p ticularly liable to arise in patients whose resistance h been lowered by debilitating conditions

The pathological features of staphylococcal pneumon are the development in one or both lungs of one or mor areas of massive consolidation showing hæmorrhage and early abscess formation These abscesses are often multiple *Staphylococcus pyogenes* can be cultured as the predominant organism from the lungs Clinically the disease is often characterised by an insidious onset, but it may begin suddenly with chills and rigors Associated upper respiratory infections are common Pleuritic pain sometimes occurs Fever is often high and remittent, with tachycardia, dyspnœa and cyanosis There is often severe prostration, particularly in children and in influenzal patients Diarrhœa appears commonly in infants At first the physical signs are those of bronchopneumonia Evidence of consolidation may soon develop over one or more lobes Later the clinical features of lung abscess may manifest themselves Th sputum is purulent and may be bloodstained or ru and in influenzal cases is sometimes salmon pink I contains staphylococci, either alone or as the pr dominant organisms, and is often copious when absce have developed If the patient does not die in the fi few days of his illness an empyema commonly develo Staphylococcal pericarditis and acute nephritis a occasional complications The disease often last long as a month in cases which recover The fatality high, particularly in influenzal and debilitated cases a in children Thus it was noted by Chickering in t 1918 epidemic that though the staphylococcal ca constituted only about 10% of the total pneumon they were responsible for approximately half the dea Kanof and his colleagues noted a fatality of 73% in h series Macgregor reported 10 successive cases in childr with no recoveries Reimann, on the other hand reported 6 patients with only 2 deaths Leucopenia and high, sustained fever are ill omens in prognosis

There have been few reports of the results of su phonamide therapy in staphylococcal pneumon Blake and Haviland (1939) treated 6 cases (3 with positive blood-cultures) with sulphapyridine Only patient recovered and this case had a negative bloo culture Maxwell (1938) reported a cure with sulph pyridine in a case of staphylococcal septicæmia wi pneumonia The sputum of this patient, howev contained pneumococci Weisman and Russell (19 described 5 cases of staphylococcal laryngotrache bronchitis in infants treated successfully with sulph methylthiazole , 3 required tracheotomy, but desp this measure their condition continued to deterior until they were given the drug Kammerer (1941) mentions a case of staphylococcal postoperative aspi tion pneumonia with multiple lung abscesses which wa cured after sulphamethylthiazole therapy In a ser of 50 cases of staphylococcal infection treated wit sulphathiazole which I reported recently (Melton 1941) I observed that in patients suffering from multi pyæmic lung abscesses the drug seemed to have little effect, but 4 patients with staphylococcal septicæmia developed pulmonary complications which cleared up satisfactorily The present report concerns 4 othe patients with staphylococcal pulmonary infections, 3 of imated from an equation in which the total " thera- tic units " multiplied by 100 are divided by the mber of weeks of treatment the answer being the so- led " efficiency index." Given that treatment is ministered for the number of weeks recommended for e stage of the disease, and an efficiency index of 60 or ore, the patient is regarded as having had sufficient atment The average clinician may feel rather eptical of this attempt to estimate the patient's action to treatment in terms of a mathematical rmula, but the procedure has stood the test of Colonel urke's experience and so commands respect It may questioned whether his classification of the stages of philis has much advantage over the Ricordian classifi- tion on which fundamentally it is based Despite ese criticisms the book is able and stimulating It is be hoped that it will not be allowed to pass into livion as a result of the author's untimely death

Medical Societies

NUTRITION SOCIETY

THE first scientific meeting of the society was held in e Physiological Laboratory Cambridge, on Oct 18 r CHARLES MARTIN F R S , took the chair at the orning session and Sir JOSEPH BARCROFT, F R S at e afternoon session In an introductory address Sir OWLAND HOPKINS, F R S , pointed out that the need r a nutrition society had long been felt The subject as becoming so large and its implication so wide at it was no longer practicable to consider it as a bsidiary branch of biochemistry or physiology More portant perhaps was the need for closer collaboration tween the laboratory worker and the clinician between e public-health worker and the dietitian between ose concerned with human nutrition and those con- rned with animal nutrition Such coöperation was ssible and a society such as this could bring it about he secretary, Mr Leslie J Harris D Sc read messages goodwill from American nutritional workers and many nglish societies The meeting took the form of a mposium on the evaluation of nutritional status his was discussed under three heads · the assessment the level of nutrition in man; the clinical signs of etary deficiency , and the nutrition of farm animals

ASSESSMENT OF LEVEL OF NUTRITION IN MAN

Dr HARRIS reviewed the laboratory methods which ive recently been evolved for the study of nutritional atus in man There were many reasons he said why ch tests were of use—they could detect signs of ficiency earlier than was possible by clinical examina- on , even if no deficiency existed it was often useful determine whether the reserves of a nutritional factor ere high or low , the final symptoms of deficiency (for ample, avitaminoses C or K) often occurred so sud- nly that it was of considerable advantage to detect e possibility of their approach ; lastly, the existence of rtial deficiency in itself, while not necessarily causing vious signs or symptoms must result in some degree of health Dr Harris brought forward evidence for the ality of " partial deficiencies " The fact that frank riberi or scurvy were rare in this country or even that rsory examination revealed no sign of malnutrition, is not sufficient to prove that partial deficiency did not ist The standards used in assessing malnutrition re often either inadequate and variable—such as the ethod of classification of nutritional status in school- ildren—or were too low, as for example were the past ight and height averages for children The adminis- ation of iron to " normal " babies or of extra milk to normal " school-children has resulted in considerable provement in health and physique He then des- bed the methods which were available for the detection partial deficiencies of different dietary essentials and ve examples of their use By the urinary excretion thod (the so-called " saturation " test) of measuring amin-C reserves it was shown that school-children in a or district in Cambridge were lower in respect of vita- n-C nutrition than those from a well-run home for aifs and strays where the diet was adequate The serves of the vitamin were also found to be higher at e end of the summer than in the early spring. Large groups of children given various graded supplements of vitamin-C showed corresponding graded levels in their " reserves " as measured by this method. Low levels of vitamin C were found in patients with acute infectious diseases, in those on " gastric diets " and in lower economic classes Tests such as these were being developed also for vitamin B_1 and nicotinic acid and they offered a reliable method of obtaining exact information about the level of nutrition of individuals or groups of individuals in the community in respect of specific nutrients

Dr H M SINCLAIR spoke of the necessity for caution in interpreting the results of saturation tests Alterations in renal threshold rate of storage or rate of metabolism might conceivably affect the quantity of vitamin excreted in the urine, apart from the degree of saturation of the tissues The postabsorptive level of a given vitamin in the blood was probably of greatest physiological significance since this determined the amount available to the cell In attempting to assess accurately the nutritional status of individuals or groups an exhaustive investigation was essential—clinical, clinico-laboratory and special tests in blood and urine He gave examples of the methods by which nutrition surveys of this sort were being conducted in America

Dr JOHN YUDKIN gave an account of some recent surveys of the incidence of dark adaptation which he had been carrying out in collaboration with Mr G W ROBERTSON, B Sc. Poor dark adaptation in single individuals may be proved to be due to deficiency in vitamin A by the improvement which occurs when the vitamin is given In comparing large groups of people, however a comparison of the proportion in each group whose dark adaptation is good, bad or indifferent is sufficient to show the relative status of these groups as regards vitamin-A intake Thus, in a study carried out in children from three Cambridgeshire schools, 60% of the children from two of the schools, and only 35% from the third school were classed as having good dark adaptation In adults, it is necessary to compare groups of similar age since there is a deterioration of dark adaptation with age In three groups of young people below the age of 22, two of them—nurses and medical students—showed 80–90% who had good dark adaptation, while the third—workers in a Midland factory—contained only 55% in this grade The factory workers were also examined as to their hæmoglobin levels Nearly 800 subjects were investigated more than 30% of the women and some 6% of the men had definite nutritional anæmia

CLINICAL SIGNS OF DIETARY DEFICIENCY

Dr. B S PLATT stressed the point that the nutritional level at which clinical symptoms appeared was definitely lower than that at which optimal health is maintained The detection of deficiency diseases rested not only on accurate examination but also on the response to specific therapy or on the improvement following a generally increased standard of nutrition Illustrating his remarks with photographs, Dr Platt pointed out some of the features of deficiency diseases as seen by him in China and Africa In some instances the introduction of some simple dietary measure produced impressive results The change, for example, to unwashed from washed rice in certain factories in Shanghai led to a considerable fall in the number of employees who had to give up their work. Dr Platt emphasised the association between deficiency and infection He referred also to the high incidence of infestation with the bed-bug found in people suffering from cheilosis Finally, a great deal might be learned from the study of the general behaviour of subjects the apathy and listlessness found in malnourished children contrasted greatly with the exuberance and high spirits of their better nourished neighbours

Dr R H DOBBS dealt with the assessment of the nutritional status of children Adequate assessment must be made on the basis of physical examination general behaviour (particularly as described by the mother and teacher) and the existence of special evidence of malnutrition Of particular value in the physical examination was the condition of the skin, the musculature (including stance and posture) and the teeth. Apathetic behaviour poor appetite and undue fatigu-

Reviews of Books

Diseases of the Heart

Diagnosis and Treatment HENRY A CHRISTIAN, M D, F A C P, Emeritus Hersey professor of the theory and practice of physic, Harvard University London Humphrey Milford, Oxford University Press Pp 599 35*s*

THE name of H A Christian on the title-page of a medical book is sufficient guarantee of its clinical soundness, and this reprint from the " Oxford Monographs on Diagnosis and Treatment " is no exception Based largely on Dr Christian's personal experience at the Peter Bent Brigham Hospital and in consulting practice, it presents an able and coherent picture of clinical cardiology True to his title, he emphasises diagnosis and treatment rather than ætiology, but enough is said to ensure that the reader has some idea of current views on causation The common conditions met with in practice receive most attention, but rarer conditions are not overlooked and there is a succinct chapter on glycogen disease, amyloidosis of the heart, and other such unusual findings The references are confined to American literature, and it is good to know that despite the international situation we are still able to receive exports such as this from our American colleagues

Diabetic Manual

(7th ed) ELLIOTT P JOSLIN, M D London Henry Kimpton Pp 229 10*s* 6*d*

THE appearance of the seventh edition of this book is a good indication of its popularity on both sides of the Atlantic In the simplest of language a remarkably complete picture of diabetes mellitus is given to the reader , by the use of homely examples the details of treatment are made clear and the possibilities of misunderstanding are reduced by a series of questions and answers which show real comprehension of the patient's difficulties But perhaps the greatest virtue of the book lies not in the competence which it displays in setting forth technical knowledge but in its attitude to diabetes as a personal problem Its whole tone is one of hope , and it would appear impossible for a patient to study this manual without realising that, far from being at the mercy of a mysterious illness, he is in fact master of his own fate

War-time Health and Democracy

HUGH CLEGG, M B Camb , M R C P London J M Dent and Sons Pp 64 1*s*

A CHANGE has taken place in the professional attitude to subjects which a few years ago were dismissed almost without discussion Proposals for state and socialised medicine are receiving a more sympathetic hearing The war is naturally the precipitating factor in this changed attitude, but wider economic forces have created the possibility of change That the situation does not affect only a minority is shown by the B M A Planning Commission, which by its very existence has put it on record that somebody should do something Dr Clegg sets out to describe how the medical profession met the problems created by September, 1939, how the war affected the national health, and how the health problems which arose have been tackled He gives a broad survey, well spiced with facts and figures The title arose out of Lord Hewart's definition of democracy as a system of Government which allows " within agreed limits freedom to criticise " , and the author holds that any system of state medical organisation which shackled this freedom would harm medicine and the people it serves He points out that after this war the individual doctor will have to work in closer cooperation with his fellow doctors rapid extension of medical knowledge and techniques compel this, Medical care will have to be administered to the patient by larger medical units, and in these the doctor will have to surrender some of his present freedom of action " So long as initiative and imaginative thinking are not put into halters by a system that plays for administrative safety, the medical man will gain more than he will lose "

Although the book is written for the general public, it is of considerable interest to the medical reader, who may be slightly startled to see in cold print " No medical service can be other than a repair shop for damaged human machines so long as the people of dem England live in a state of economic insecurity, inadequately fed, and are badly housed " Yet Dr Cleg believes that " the doctor, in relation to his professio work, should steer clear of politics If after caref investigation he concludes that poverty is the root ca of certain diseases and ill-health, his job is to point th out, in season and out The cause of poverty is a matte for political thinkers and economists " This seems somewhat introverted view of the doctor as a democra If we have built a state in which poverty breeds ill heal we have all had a hand in doing it, doctors and layme alike , and the duty of undoing it must also be shar It is not pleasant to picture the medical profession a sort of encapsulated tumour—benign, no doubt, but c off from a responsible part in the activities of the bo politic

Periodicity and Cause of Cancer

J H DOUGLAS WEBSTER, M D Edin , F R C P E, F F honorary director, Meyerstein Institute of Radiothera Middlesex Hospital, London London Bailliere, Tind and Cox Pp 178 12*s* 6*d*

IN following up the experimental observation th periodicity or rhythm in the rate of growth of transplant tumours is sometimes conspicuous, Dr Webster h endeavoured to show that similar fluctuation occurs i human cancer He claims that regular and predictabl fluctuations in growth-rate, time of recurrence and metastasis are characteristic of many carcinomas and sarcomas, and also of leukæmias and Hodgkin's disease The evidence for this claim is set forth in a large number of case-histories, but it is nowhere very clearly stated exactly how the onset of increase or decrease in growth rate is determined nor the date of appearance of a recurrence or metastasis Dr Webster appears to depend upon the observations and complaints of the patients , but he claims to find an almost mathematic ally exact periodicity even with such an erratic source of information, and to have been able to predict the date of onset of a change in growth-rate, a recurrence, or the appearance of metastases in a number of patients In those cases where predictions were made the patient were told to present themselves for examination at th time the change was due and the author believes th predictions were correct to within a week in 60 cases

Venereal Diseases

E T BURKE, M B Glasg director of L C C Whitechap clinic London H K Lewis and Co Pp 549 30*s*

THIS book is well prepared, well written and we illustrated , it is uncommon to find a textbook on an subject so readable from beginning to end Much of th teaching is orthodox, but Colonel Burke held som interesting unorthodox views , it is perhaps unfortuna that he used this medium for stating them so strongl He maintained, for example, that the gonococcus i urethral pus, far from being the intracellular victim o phagocytosis, is attached to the outer wall of th leucocyte and achieves its greatest virulence and mo rapid growth in this situation , and he suggested th the gonococcus may be a harmless symbiote, perhaps normal inhabitant of the genital tract, which becom pathogenic only on occasions These are no more th theories , certainly no strong evidence is here produc to support them and they cannot be said to explain th facts even as well as the accepted views

In the treatment of syphilis he strongly advocated th alternating continuous use of arsenicals and bismut rather than the concurrent intermittent method wh has found greater support in this country He recor mended abnormally heavy doses of arsenicals, giv over longer periods than are customary , but the tot duration of the treatment advised for early syphilis shorter than is generally held to be safe His schem of treatment have the disadvantage that the patient required to attend three times a week for most of th period of treatment, and that no bismuth is given for th first three months, during which default is most com mon For each preparation of arsenic and bismuth figure of relative value is worked out, based on the " chemotherapeutic index " or the relationship of the minimum single curative dose to the maximum sing tolerated dose The effectiveness of treatment i

LONDON SATURDAY, NOVEMBER 1, 1941

NATIONAL WAR FORMULARY

THERE was a time when a doctor could achieve a ir reputation as a prescriber by the liberal use of harmaceutical cocktails such as the compound ncture of cardamon, and by avoiding the more pectacular catastrophes of incompatibility represented by explosive mixtures The advent of ational health insurance, by curbing extravagant prescribing, showed many practitioners the error of heir ways, and not a few physicians were content to ang the blunderbuss in the hall and practise polyharmacy no more Modern war, which is fought as avagely in the realm of economics as on the battleield, has now forced all doctors to exercise more discrimination when prescribing The therapeutic equirements committee of the Medical Research Council stated the position succinctly in their memorandum[1] "Economy in the use of a drug may be necessary in war-time because the drug is imported or because its manufacture at home diverts materials and skill from other essential services" The committee classified drugs into those which we can or must use freely (A), those with which we must be careful (B), and those which we must give up altogether (C) Based mainly on this classification a National War Formulary[2] will shortly be issued by the Ministry of Health, and its importance can hardly be overstated The general practitioner is specially concerned, for the N W F will replace the National Formulary for N H I purposes on Dec 1, before which date all nsurance practitioners and pharmacists will receive a copy But the new formulary is not intended exclusively for N H I patients, as its children's section bears witness, it is hoped that all practitioners will amiliarise themselves with the N W F and use it when prescribing for their private and hospital patients as well

Comparatively few doctors are sufficiently well nformed on the dry bones of materia medica to appreciate the more subtle reasons for avoiding this or hat drug as a contribution to the war effort They will therefore be glad to have the guidance of the section on war-time prescribing The reasons for some of the "Don'ts" are at once apparent, particularly those referring to confections, glycerin and alcohol On the other hand, it will come as a surprise to many that they must go carefully with such commonplace substances as linseed, starch and soap liniment (high alcohol content) We referred last week (p 489) to the urgent need for economy in aspirin, and this is mentioned in the formulary, though it includes mixtures and tablets containing aspirin If the results of recent research[3] are accepted, it follows hat five grains of aspirin have as powerful an analgesic action as ten There seems therefore to be no pharmacological justification for the practice (as common among doctors as laymen) of taking "a couple of aspirins", the essential thing is that the dose should be absorbed, by grinding it up, chewing it or taking it in suspension There are some helpful remarks on proprietary preparations, the abuse of which has become the blight of modern therapy To quote the formulary "Before prescribing any proprietary preparation the medical practitioner should consider carefully whether the needs of the patient would not adequately be met by the use of a drug or preparation which is identical or of reputed analogous therapeutic effect Particularly should he refrain from prescribing proprietary preparations of foreign origin" Because of skilful publicity and their convenience these preparations tend to accumulate in the doctor's therapeutic armamentarium, and the prescriber is likely to continue to use the original trade-name long after the identical substance has become official—usually under a name which has some bearing on its composition but not necessarily easier to remember on that account There can now be no excuse for such extravagance

In this country we are well supplied with works of reference on materia medica, but our B P, our B P C and our Martindale tell us little about the relative effectiveness, availability and cost of the preparations they describe Sweet indeed are the uses of adversity which has compelled a committee of distinguished medical men and pharmacists to come to grips with these aspects of prescribing The advice which the N W F offers has been made necessary by the difficulties of supply, but there has clearly been a careful search among pharmacological title-deeds in deciding the claims of each drug Exception can be taken to few of the successful candidates, though it is difficult to justify the inclusion of opium in a lotion, the addition of sodium bromide to the sleeping draught containing chloral hydrate merely spoils the end-point of the latter drug, and mist brom et arsen is based on the long-exploded belief that a small dose of Fowler's solution prevents bromism There is a welcome departure from the so-called classical prescription, with its tiresome insistence on basis, adjuvant, corrective and vehicle, and there is evidence of a determined effort to eliminate superfluities and go straight to the point A diagnosis having been made and drug treatment decided on, this booklet shows how simple it is to prescribe for the patient The legacy of elaborate polypharmacy bequeathed to us has here been decisively repudiated; let us hope that this wholesome decision, forced on us by the war, will remain ours by choice with the return of peace

INSUFFLATION OF THE FALLOPIAN TUBES

SINCE the procedure was first described by RUBIN in 1920 insufflation of the fallopian tubes has been largely practised by gynæcologists in this country, and various modifications of RUBIN's original apparatus have been made, notably those of BONNEY and PROVIS This minor operation, however, largely because of its simplicity, is sometimes misapplied. KING,[1] who surveys his results in 635 insufflations, sets up six indications for insufflation—as part of a routine investigation in cases of primary and secondary sterility, as a help in the differential diagnosis in obscure pelvic conditions, to determine the state of the residual tube after salpingectomy for any reason,

Economy in the Use of Drugs in War-time M R C War Memorandum No 3 1941, p 3

H M Stationery Office Pp 70 6d

[1] King, G Caduceus, 1930, 19, 161

ability would affect school progress and afforded a guide to general ill-feeding Malnutrition might also be suspected from "external evidence" such as the family income or a history of artificial feeding without due care to supplement the diet with, for example, iron in one or other form Conditions of stress were important in accentuating the effects of defective nutrition Growth in childhood provided such stress and infection increased it, making it all the more important to assure the adequate nutrition of the child

The question of physiological stress was underlined by Dr W C W NIXON The increased demands of the body during pregnancy might well be sufficient to reveal a border-line state of deficiency In Hong-Kong, beriberi frequently made its appearance during the latter half of pregnancy Vomiting in the early stages might increase the deficiency of vitamin B_1 Such mild and often neglected complications of pregnancy as œdema and pins-and-needles might well be due to mild deficiency of this vitamin Many women dying of beriberi during pregnancy had had œdema for a month or two before the diagnosis was obvious Recalling the incidence during pregnancy of dental caries, anæmias, cramps, œdema, fatigue and pins-and-needles, Dr Nixon asked whether, in the light of newer nutritional knowledge, it was not more likely that they were all signs of inadequate nutrition rather than necessary physiological concomitants of the pregnancy state

NUTRITION OF FARM ANIMALS

Mr C CROWTHER, Ph D , began by comparing the problems of animal nutrition with those of humans The nutrition of farm animals was concerned chiefly with attaining as economically as possible a specific product This did not necessarily involve the optimal nutrition of the animal and indeed might intentionally produce a pathological state The worker in animal nutrition had many advantages over his colleagues studying human nutrition His subjects offered a much greater freedom in experimentation, were more passive and hence less likely to interfere in the experiments, and lastly were much more uniform as regards genetic constitution On the other hand, in determining the adequacy of an animal diet it was difficult to assess the quantity of available carbohydrate since cellulose was in part assimilable The problem of the protein, too, was complicated in ruminants by the bacterial synthesis of non-protein nitrogen into amino-acids The calculation of the energy value of the diet was also more involved than with human diets The problem of supplying specific sources of vitamins did not often arise in the nutrition of the farm animal, especially when grazing In considering the effects of such supplements, it was necessary to bear in mind the other constituents of the diet, since their effects were often more than simply additive

Mr H H GREEN, D Sc , reviewed some of the commoner deficiency diseases of animals Vitamin deficiencies were not common except in animals intensively reared in stables, batteries or styes In such conditions, deficiency of vitamin D might occur in poultry and of nicotinic acid in pigs Mineral deficiencies, on the other hand, were not uncommon Aphosphorosis, for example, was well known in South Africa Deficiency of the trace elements—copper cobalt and possibly manganese—also occurred Swayback disease amongst lambs appeared to be due to deficiency of copper, and possibly also of cobalt

Mr JOHN HAMMOND, D Sc , F R S , discussed the question of the total energy and protein of the diet Animals kept on a low plane of nutrition for a short while after birth are not only smaller than normal at the end of this period but go on being small into adult life The weight of animals fed for long periods on a low plane of nutrition may be less than half that of litter mates receiving a larger amount of food Not only the size of the body but also the relative proportions of the different parts are greatly affected by controlling the food intake at different levels These effects, too, produced in young animals, may persist to adult life even if the diet has subsequently been increased

DISCUSSION

Prof J L MAXWELL, M D , stressed the importance of detecting early signs of deficiency He suggested that pain in the back and legs, and instability in walking of occurring in pregnancy were possibly early signs vitamin-D deficiency It was necessary also to bea mind that deficiencies were likely to be multiple ra than single

Prof E -J BIGWOOD said night-blindness in Au tri 1918 appeared first in pregnant women, another exa of the effect of pregnancy revealing a latent deficien In a prisoners' camp in Germany the Russians devel scurvy and the Rumanians developed pellagra altho all were given the same deficient diet With regard the question of saturation with a factor such as vita C, it had often been asked whether this was neces identical with the optimal intake If guineapigs, on the few species of animals which can develop scurvy, a allowed a free choice of diet they become satura with vitamin C Moreover, the amount of the vita in the blood reaches the same level as that of ot species of animals in whom scurvy cannot be p duced but for whom nature synthesises the requ vitamin C

Dr DAGMAR WILSON appealed for the standardisa of the signs of early deficiency so that workers could trained, as in India, to recognise them easily She h been able to recognise several cases of angular stoma in Oxfordshire school-children

Mr GEOFFREY BOURNE, D Sc , pointed out that amo the early signs of vitamin-B_1 deficiency were increas irritability, lassitude and a general deterioration i mental alertness In the detection of early deficiency he had found the Gothlin test for capillary fragility of use in showing a lowered intake of vitamin C in patients with peptic ulcer

Mr S K KON, D Sc , suggested that a further test for malnutrition was the estimation of vitamins in the milk of nursing mothers Tests already begun showed that there was a considerable drain on the vitamin reserves of the mother and that the amount of vitamin is now considerably lower than that found in 1934 by Dr Harris

Prof H D KAY, D Sc , said that although as Dr Crowther had pointed out the provision of extra suppl of vitamins was not perhaps essential for all classes farm animals it would considerably affect the nutrit value of the animal product as far as their use in hum nutrition was concerned Thus, the amount of vit A in milk was dependent to a very large extent on amount ingested by the cow

Prof OTTO KESTNER recalled some of his work protein deficiency in Germany in the last war He pointed out that while vegetable proteins might singly of low biological value, together they might act com mentarily so that defects in one might be made by another

Dr S W SWINDELLS hoped that one of the obj of the new society would be to disseminate accu knowledge of nutrition

Dr E H WILKINS looked forward to the adoption simple tests for malnutrition and mild deficiencies wh would be easily applicable by medical officers of hea He instanced the importance of a study of posture children as a guide to nutritional status

Dr ROBERT SUTHERLAND wished to see empha aspects of nutrition which would lead to the adoption generally satisfactory diets, rather than those which to the development of studies of deficiency diseases, assessment and then specific cure

Sir JOSEPH BARCROFT, referring to the present sta of laboratory methods in the diagnosis of defici disease, recalled the similar position which arose af the introduction of such diagnostic aids as the elect cardiogram by Mackenzie and Lewis Clinicians w at first sceptical as to their usefulness, but th mainly because the apparatus was costly and the t nique specialised He felt that laboratory method the study of malnutrition would soon reach a state recognition and applicability comparable to that enj today by the technical methods used in cardiology far as the question of the separate study of the va nutritive factors was concerned, he felt no apprehen that this would detract from a proper study of malnu tion as a whole He looked forward to the time whe knew enough [illegible] synthetic diet as embolism are much less in the conscious than the sthetised patient, for the diagnosis is immediate ne one and masked in the other. On the thera- ic value of insufflation KING is wisely guarded in claimed that 17 5% of his sterility cases became gnant after the operation, and nearly half of these under two months, an observation confirmed by ny subsequent writers Such a result is more pirical than scientific yet the figures are impressive conclusion must be that insufflation is a useful cedure, that it should be carried out as an out- ient rather than an inpatient operation, that a nographic apparatus gives the best and only tain evidence of the functional behaviour of the es, and that if due regard is paid to the indications l the danger signals it is safe

THE MENTAL HOSPITAL PICTURE

IT is not perhaps generally realised how great a ntribution the mental hospitals of the country have ide to the Emergency Medical Service Large mbers of beds had to be found at the outbreak of r, and a considerable proportion of them were ovided by the mental hospitals, some of which were ptied for the purpose, while others renounced asured new blocks or sizeable annexes Most of e big mental hospitals have given up a quarter of eir beds This meant that patients had sometimes be overcrowded Moreover, shortage of nursing id medical staff, darkening of wards by protective ast walls and blackout curtains, and other unavoidble war restrictions have impaired standards in eatment and living conditions At one large hostal, for example, a modern block for newly admitted ses and a newly opened villa for convalescent tients were vacated and handed over to the E.M S , provide 250 casualty beds and a nurses' hostel hereafter treatment of early mental cases had to be rried on in the wards of the old hospital, where rading and segregation were difficult In this hosital, as elsewhere in the country, the number of oluntary patients admitted has fallen, but the reducion does not indicate that facilities for the treatment f such patients have been seriously limited; cerainly in the London area not a single application or voluntary treatment has been refused through ack of accommodation Taking the country as a whole, 100 admissions are made up of 40–60 certified, 0–12 temporary and 30–40 voluntary patients he falling off in total admissions that has been reported reflects the common experience that war does not increase the incidence of psychosis and neurosis n London the drop in new admissions has been far reater than it was in the last war, probably owing to vacuation Nevertheless, in some areas, patients who for social reasons ought to be in a mental hospital re not being accepted, or are being discharged, because medical superintendents say quite fairly that hey must keep their accommodation for the acuter ases These less acute patients may be found causing mild difficulty in their homes or in reception areas by behaviour which would not be tolerated in peace-time On the other hand, many patients of both sexes with relatively mild mental and emotional disorders are being absorbed into regular employment, and are nding occupational therapy in jobs for which in peace-time they would never be taken on, and perhaps in time to come we shall have to plan the rehabilitation of psychopathic people on the lines thus artificially produced by war It is possible, of course, that more patients who would normally seek treatment as voluntary cases in hospital are being seen and treated at outpatient clinics, of which there are 203 distributed over the United Kingdom and Northern Ireland , but no such increase has been reported Indeed, in many of the clinics situated in large cities there has been a decided falling off in attendances as a result of evacuation In general the position is that the mental hospitals though hampered by the sacrifice of accommodation which has been made to the E M S , by shortage of doctors, and even more serious shortage of nurses are standing up bravely to their job, and deserve much credit for maintaining a vital social service approximating to peace-time standards under heavy difficulties

SCHOOL MEALS

OF the five million children in our elementary and secondary schools only 300,000 are now getting a meal at school and, while in some areas school meals are provided for a third of the children in others there is no provision at all In the reception areas children often have to travel several miles to school with no chance of returning to their temporary homes for a midday meal , if there is no meal at school they have to subsist on frugal packet lunches put up by harassed foster parents These nosebags were inadequate in peace-time and must be more so now when cheese and meat are scarce foreign fruit has disappeared and home-grown substitutes are expensive Moreover, with the vastly increased employment of women in munitions there is often no-one to prepare meals at home and supervise their consumption As speakers in the Women s Parliament pointed out in their session reported on another page, universal school meals would not only be a great step towards ensuring adequate nutrition of our children, but would also release more women for industry than any other measure In the House of Lords on Oct 21 Lord WOOLTON foreshadowed a rapid expansion in school-meal organisation The Exchequer is greasing the ways with an additional grant of 10% towards their cost, making the average rate of grant 80%, and school canteens are to receive priority supplies of food The cooking depots which local authorities have been holding in readiness for feeding the community if communications or normal domestic arrangements were put out of action are to be adapted for the children, and the British Restaurants are also to help with cooking school meals Where new kitchens must be started local authorities will be able to draw on the Ministry of Food's central pool for their equipment

These steps are encouraging, but as the *Times* pointed out in a leading article on the morning of Lord WOOLTON s announcement it will hardly be possible to provide a midday meal for all schoolchildren in war-time unless some English variant of the Oslo meal is adopted This has already been attempted successfully in the East End of London, in Glossop and elsewhere The theoretical principle behind the Oslo meal is that if at one meal in the day highly protective foods, chosen from dairy foods, greengroceries, the oily fish and whole cereals, are given it will not matter much what foods are chosen by the child s parents for the rest of the day The to confirm the success of a sterilising operation , as a routine after salpingostomy or uterotubal implantation , and as a therapeutic measure in maintaining or improving tubal patency His four contra-indications should be noted First and foremost is menstruation or any other type of uterine bleeding The only proper time to perform insufflation is in the week succeeding menstruation , if this rule is broken safety is sacrificed and the test is vitiated Yet how many hospital insufflations are done haphazard at any time in the intermenstrual phase ? Secondly, any acute or subacute pelvic inflammation, notably cervicitis, for here the danger of retrograde infection is very real The third and fourth—pregnancy and severe constitutional disease—are self-evident

KING's technique differs from the accepted practice in several important points, the most striking being that he eschews special preparation and anæsthesia and performs his insufflation in the outpatient clinic This alone saves patient, surgeon and institution much time and money and his results and those of American gynæcologists conclusively prove the safety and efficacy of the proceeding A careful bimanual examination is made to rule out any pelvic contra-indication The patient is then placed in the lithotomy position, suitably draped, and the vagina, cervix and cervical canal are carefully cleansed with an antiseptic such as 5% mercurochrome or Dettol A uterine sound is passed after gently grasping the cervix with a fine volsellum, and this gives minimal discomfort to all but the most nervous patients A special uterine cannula with a gas-tight joint at the cervix is inserted and an assistant turns on the gas KING uses carbon dioxide and limits himself to a flow of 30–60 c cm per minute, and this in normal cases should be all that is necessary to demonstrate patency , he never exceeds a pressure of 200 mm of mercury The apparatus is so connected that the behaviour of the tubes is recorded permanently on a kymograph While the investigation is proceeding the assistant auscultates both iliac regions for the intra-abdominal passage of gas, while the operator sees that no leakage takes place at the cervix, watches the recording needle and keeps an eye on the patient The resultant graph will divide patients into four main types normal patency, tubal spasm, tubal stenosis and complete tubal obstruction In cases of normal patency, and these comprised 50% of KING's series, gas passed at a pressure of under 100 mm and well-marked oscillations at the rate of 3–5 per minute were recorded on the kymograph, due to normal tubal peristalsis The presence of these waves, which increase in frequency and vigour as the time of ovulation approaches, establishes normal behaviour of the tubal musculature beyond doubt The graph obtained with one patent tube is no different from that with both patent , hence the importance of auscultation on each side of the abdomen KING only encountered tubal spasm in 3 5% of his series, and this figure agrees closely with that of RUBIN Here the gas does not pass until a high pressure is reached, sometimes approaching 200 mm of mercury Thereafter it passes readily and the graph then obtained differs in no way from that of a tube of normal patency It is doubtful whether any clinical importance is to be attached to tubal spasm, and to overcome this some workers give a routine dose of atropine before examination

In cases of tubal stenosis, where inflammation thickened and fibrosed the tubal wall with fo of strictures or kinks, with or without peri adhesions, the kymograph will show absence or impairment of peristaltic activity This occurred in 12 5% of KING's series, and he rightly points o that in this class of case Lipiodol injection will gi a normal picture, yet this is the very tube that most likely to be associated with sterility, sin though patent it is largely functionless or subfunctional Insufflation in these cases is often painfu probably from the stretching of adhesions, whe in normal patency it is as a rule painless Tub obstruction was encountered in 34% of KING's cases, a figure which again agrees with that of RUBIN Such an obstruction may occur at the cornu, in th tube, or at the abdominal ostium If at the corn no gas passes, of course, and the patient experien a midline pain of uterine distension If the obstruc tion is at the abdominal ostium the pain may b referred to one or other iliac fossa The gra obtained in tubal obstruction is characteristic, wit a flat plateau at or near 200 mm Hg, which i sustained until the gas pressure is released Certain symptoms may be experienced by the patient during the test There may be slight pain as the uterus and tubes are distended with gas, passing off as the gas enters the peritoneum , more severe central lower abdominal pain or iliac-fossa pain usually indicates a blockage at the cornu or the abdominal ostium respectively Any severe pain is a signal to stop the examination Shoulder pain is diagnostic of pneumoperitoneum and thus of tubal patency It was noticed by KING in 157 patients, especially when they assumed the standing position at the conclusion of th examination , it was invariably slight and transitor and often not remarked on unless a special questi was put In all cases of patency an X-ray or scre examination will reveal gas under the diaphragm

Certain dangerous sequelæ occurred in 17 of KING' cases Many of them were mild, such as nausea i 5 cases, vertigo in 3, fainting in 1 and a hysterical attack in 1 In 5 cases there was severe pain, probably due to the presence of hydrosalpinx, which i naturally a contra-indication to insufflation The were 2 cases of suspected gas embolism, a dange which has been used as an argument against insuffl tion Both of these patients quickly recovered I the first a pressure of 200 mm Hg was used and o rising she complained of malaise and precordial pa and started to cough violently, producing a modera amount of blood-stained frothy sputum She had rapid pulse and was cyanosed After 20 minute these symptoms passed and after resting another minutes she was allowed up and felt well A tentative diagnosis of gas embolism of the utero-ovarian vei was made The second case was similar except that the patient had a slow pulse of 40 , she recovered i 4 hours Both these patients had blocked tubes and both were insufflated rather late in the cycle, on th 11th and 16th day The lessons to be learned fro them are that in tubal stenosis prolonged insufflati is dangerous and the amount of gas used should n exceed 50–75 c cm If any unusual symptoms ari during the test it should be stopped at once If the operator is alive to the dangers and contra-indications there is no reason why these unpleasant reaction should deter him from its performance The dangers experimental wounds A disc of rabbit blood-clot s introduced into a pocket made between the dense rous layer deep to the platysma and a similar sheet vering the deep musculature of the haunch on either le On one side 0 25 g of the drug was also inserted ctions of the wounds were examined at various stages healing up to 2 weeks Glynn found no histological idence that any of the three sulphonamides inhibited e formation of collagen or pre-collagen fibres, or the velopment of new blood-vessels The macrophage sponse likewise did not seem to be impaired though ere was evidence of diminished phagocytosis in the eated wounds Sulphathiazole and sulphapyridine ersisted in crystalline form up to 5 and 7 days respecvely but the sulphanilamide was completely dissolved ithin 24 hours An attempt was also made to estimate e quantitative effects of these sulphonamides by broblast counts at 5, 7 and 14 days With sulphanilmide no significant difference was found on comparing he treated wounds with their controls, a very slight hibition of fibroblast proliferation could be attributed o sulphapyridine and sulphathiazole On the other and, sulphanilamide was found to have a slight but efinite toxic action on striped muscle Sulphapyridine ad a still slighter action while sulphathiazole had none t may thus be concluded that while it is safe to use all hree drugs in the local treatment of wounds, it would be referable to use sulphathiazole for wounds of the face, ands and forearms where the minimum of scarring is esirable

MUSCLE ATROPHY

The reaction of a muscle to the severance of its nerve s as a rule divided into three phases In the first period, asting about a week, there are few changes in the muscle, morphologically or chemically But the emergence of slow contraction and rising chronaxie at the end of the first week indicate that important changes are hen taking place The beginning of the second phase s characterised by the onset of spontaneous rhythmical ontractions—fibrillation—which can be seen in the xposed muscle or where the cover is thin—e g, in the ongue by the reflected light A more delicate method or detecting, and for recording, fibrillation is the lectromyogram as Denny-Brown and Pennybacker[1] ave shown At the same time as the fibrillation starts, here begins a rapid progressive atrophy of the muscle, emonstrable in the reduction of its volume and weight he transition to the third phase is gradual, when the ross-striped substance disappears and the interstitial brous tissue proliferates the fibrillation ceases, and the uscle is gradually converted into a non-excitable and on-contractile tissue, histologically something intermediate between scar tissue and tendon

How does the fibrillation originate, and what has it to o with the atrophy? The first question is not definitely olved yet But it is known that the onset of fibrillation oincides with an increase of the susceptibility of the muscle o acetylcholine, and therefore Denny-Brown and Pennyacker assumed that the fibrillation of the muscle underoing atrophy after denervation is due to excitation of ach muscle fibre by the small amount of acetylcholine rculating in the blood This has been questioned by ccles[2] who found that curare depresses the sensitivity f the denervated muscle to acetylcholine without ffecting the fibrillation J N Langley was inclined o believe that the fibrillation took precedence over the rophy in other words that the atrophy was not one of suse but one of fatigue or exhaustion, "the muscle inadequately protected by its refractory period, driven ven to the utilisation of its own material," as Tower[3] uts it The evidence for this assumption being far from satisfactory, Solandt and Magladery[4] studied the subject experimentally They established the weight-loss curve of rat muscles after denervation, and demonstrated the presence of fibrillation by recorded action potentials They then prevented fibrillation in some of their muscle preparations by giving various drugs, of which quinine and quinidine were the most effective Atrophy still developed in all these preparations though they had never exhibited fibrillation as detected by the electrical method; hence it was concluded that the atrophy of denervation is not due to the fibrillary activity. However, the weight loss in the animals given quinidine was not quite as great as in the controls This is attributed to the fact that the quinidine induced a lethargic condition which rested the denervated muscle or protected it from mechanical injury, and this view was supported by the observation that hypnotics, while not affecting fibrillation, decreased the atrophy to an extent comparable to that brought about by quinidine The results are in keeping with the clinical experience that prevention of mechanical injury—stretching seems to be the most deleterious—may keep the muscular atrophy within limits, more important still, these experimental findings should remove the prejudice against electrical treatment of the denervated muscle which was based on Langley's theory As long as there was reason to believe that muscular atrophy was due to exhaustion by over-activity, some reserve in applying more stimulation seemed advisable This theoretical difficulty is now removed Moreover, the beneficial effect of electrotherapy no longer lacks experimental foundation Fisher,[5] in experiments on rats, found that the electrically stimulated muscle, treatment being applied for 10–20 minutes a day—showed a striking increase of weight compared with the resting denervated muscle of the opposite side

STITCH

The cause of stitch has been much debated, and the decline of interest lately does not imply that it has been satisfactorily explained The theories put forward—contraction of the spleen distension of the spleen, pull on visceral suspensory ligaments, faulty vasomotor regulation with distension of the liver and spleen in 'constitutionally inferior' subjects—were seldom formulated on first-hand information, and none of them explains every variety of stitch Capps[6] has reported the results of a study, lasting several years, of 114 attacks of stitch which he observed personally in 55 people He found them by watching the track team of Chicago University High School, men out of training at an impromptu track meeting at Northwestern University, students engaged in wrestling and basketball, and a few of his friends He also listened to what the professional coaches had to tell him Of his subjects 44 were men and 11 women, and ages ranged from 15 to 65, but only 3 were over 35 He found that the right or left upper quadrant of the abdomen was the usual site of stitch, but it might occur anywhere in the abdomen at the costal margin, at the nipple, in the precordium or—in one case—in the second left interspace The position varied in different people, and often in the same person on different occasions Some described the pain as sharp, some as dull, some as constricting, as a pressure, a cramp or a gnawing It usually passed off quickly, but might last ten or twenty minutes It was invariably brought on by physical exertion ranging from walking to strenuous running, riding, swimming boxing, wrestling skiing squash, or basketball Walking was only a cause just after a heavy meal Training had a variable effect, in 2 subjects attacks of stitch disappeared as training proceeded, in 3 others they persisted This

Norwegian public-health services, on the advice of Prof CARL SCHIOTZ, chose milk (about $\frac{3}{5}$ pint), half an orange, hard rye bread with butter and cheese, wholemeal bread and butter, and a whey cheese or cod-liver paste The meal was finished off with half an apple or a raw carrot This meal is highly protective, giving satisfactory amounts of calcium and iron and vitamins A, B, C and D It is easy to prepare and demands no cooking, so that kitchens and dining-hall can be largely dispensed with

If the authorities could be induced to envisage anything but the hot cooked meal as essential in feeding the young we should have gone a long way towards solving the problem of safeguarding the health of the school-child, for this Oslo meal is a better safeguard than the ordinary hot meal There would remain the resistance of school-teachers and parents, for the children, conservative as they often are as regards the contents of cooked meals, usually take to an Oslo meal The staff have "never heard of such a meal" and the parents are apt to feel that their children are being defrauded by being given cold uncooked foods That this kind of meal solves the problem of inadequate equipment is clear from the experience of domestic-science teachers who have been allowed to introduce a meal of the Oslo type because the demand for school meals had outrun the school equipment In one such school the Oslo meal largely invaded the province of the cooked meal English variants are not hard to devise The milk should be the same in meal, though there is no objection to giving it hot flavoured with cocoa or coffee if it is thought e that some hot food should be served Whole bread could take the place of the *Knackebrod*, a vitaminised margarine the place of butter Apples and raw carrots are still available The main problem lies in supplying what the half orange, the cheese, and the cod-liver paste supply If oranges are unobtainable watercress, mustard and cress, and raw turnip or swede will take their place, or sandwiches with filling of chopped raw cabbage and parsley may be used The cheese and cod-liver paste supply calcium and vitamin D, but these could as well be obtained from fresh herrings and sprats, or more simply from tinned herrings and salmon, and there should be no difficulty with the simplest of appliances in converting these into a paste to spread on bread If we wish imitate the Norwegians in giving a teaspoonful of cod-liver oil daily throughout the winter this can be incorporated in the fish paste In the *Times* of Oct 11 the director-general of Norwegian health services says that the significance of a hot meal has been overestimated, and it seems that all the benefit of hot food, with some others, can be obtained from a cold meal with a hot drink This looks like being the way in which school meals for all can be achieved All that is now required is imagination and the dropping of our British resistance to the unusual in catering

Annotations

BLACKWATER FEVER

THE cause of the paroxysmal hæmoglobinuria which gives blackwater fever its name has long been disputed It is known to be associated with malaria, although parasites may not be found in the patient's blood Is there a specific strain of parasites which is specially liable to cause hæmolysis of red blood-cells in excessively large quantities? Do patients have hæmoglobinuria because their red cells, possibly from long exposure to malarial attacks, are exceptionally liable to hæmolysis? Is there a hæmolysin in the patient's blood responsible for the destruction of the red cells? Foy and his co-workers[1] have tried to answer these questions by studying the results of injecting blood from blackwater-fever patients into unaffected people, and conversely by transfusing normal blood into blackwater-fever patients The results in one woman are presented in detail This was a typical case with black, acid urine containing oxyhæmoglobin and methæmoglobin, and with methæmalbumin in the blood-plasma, no malarial parasites were found in her blood Twenty-five c cm of this patient's blood was injected intravenously into a normal healthy man Eleven days later, although he had been kept strictly away from possible outside infection, the man developed a typical malarial attack and *Plasmodium falciparum* rings were found in thick films of his blood, but he did not develop hæmoglobinuria This confirmed Foy's previous experience with a series of 106 lunatics who were given intramuscular injections of blood from blackwater-fever patients, several of the recipients developed malaria, but none showed hæmoglobinuria From these results he concluded that there is no specific hæmolysing strain of malarial parasites The patient herself was given three blood transfusions from three different normal donors, and although these raised the red-cell count at first it was soon reduced to its former level, the hæmolysis continuing unabated From this it is concluded that normal cells are just as liable to hæmolysis in a blackwater-fever patient's blood stream as are the patient's own cells At the time of the transfusions the patient's reticulocyte count was low and the rise and fall of the red-cell count seemed definitely related to the effect of the transfusions and subsequent hæmolysis, later, when the reticulocytes rose, recovery set in Foy therefore infers that a circulating hæmolysin is the active factor that produces the intense hæmolysis of blackwater fever The fact that no recipient of blackwater fever blood developed hæmoglobinuria he attributes to insufficient dosage or immediate neutralisation of the hæmolysin This research has certainly cleared the ground and it is interesting that, like other workers on paroxysmal hæmoglobinurias,[2] his first conclusion points to a hæmolysin So far, however, the hæmolysin remains theoretical—its presence has yet to be firmly demonstrated Fairley, also working on this point, thinks that it is an intracellular lysin and cannot be detected by ordinary means Whatever the final answer, it is clear that the information obtainable from studies of blackwater fever can usefully be applied to hæmolytic disease in general

SULPHONAMIDES AND TISSUE-DAMAGE

REPORTS from various sources have so far indicated that the local use of sulphonamides in the treatment of wounds has little or no damaging effect upon the tissue The brain tolerates powdered sulphanilamide and sulphapyridine surprisingly well, as Russell and Falconer[3] demonstrated, and this might be regarded as a fairly severe test On the other hand Bricker and Graham[4] have found that the oral administration of sulphanilamide to dogs with experimental wounds seemed seriously to inhibit the fibroblastic response On the strength of this Glynn[5] has investigated in rabbits the local effects of sulphanilamide, sulphathiazole and sulphapyridine on the development of granulation tissue of the grown citizens were all persuaded to take part ie campaign. By the spring of 1940 the incidence of xworm in the schools had been reduced to 28% nwhile pupils and teachers had been studying soil ution and had come to the conclusion that it could be prevented, in their county, by building sanitary privies. Each child then made a report on the sence or absence of such a facility at his home, where t privy existed he reported on its site and condition, in this way a map of sanitary conditions in the nty was compiled The schools then sponsored a ject for the construction of privies Members of the ent-Teacher Association gave the lumber, the health artment provided the plans and chose the site and er bodies were responsible for labour and transport of kers Between the autumn of 1936 and the spring 1940 approximately 3500 privies were built

her studies undertaken in the schools covered immuni- ion against smallpox, typhoid and diphtheria, provi- n of school meals, a campaign for better home gardens d home canning, all resulted in a substantial advance standards, the full effects of which on health will be parent in a few years time

A similar story is told of Appomattox, Virginia, where e school-children and their mothers joined in making a rvey of the drainage and water-supply of every farm- use The value of safe water and possible sources of ntamination were studied in school, and then the ldren set about planning improvements in their home ter-supplies Finally committees of pupils visited rious farms and tried "to sell the idea of a better water- pply" As a result springs were fenced to keep cattle t, curb and housing were provided for an open well, rings were cleaned, water was piped for stock, and her practical advances were made One boy paid four rsuasive visits to a family in whose unprotected water- pply mosquitoes were breeding, he failed to convince em that something ought to be done about it, but he rned a lot about the difficulties of achieving and main- ining a high or uniform standard in public health

The report is full of stories of such victories and defeats d it is significant that the victories greatly predominate the English reader the striking thing is the plastic and endly relationship which seems to exist between icial bodies and the public Might not our own well- iced bureaucracies look askance at a public health in in which school-children were expected to play a icial and responsible part, or at a map of sanitary ilities which depended on the direct observation and port of the people using them ?

GERMAN VIEWS ON BLOOD-TRANSFUSION

IN war time as in the good old days of peace it is worth ile to find out what the other fellow is thinking or ing but this becomes increasingly difficult as foreign rnals get scarcer E Schulz, in a review of German od transfusion methods (*Dtsch med Wschr* July 18, 779), says that the direct arm-to arm technique is the t, though the fatality with this method is still 0 5% ing anticoagulants citrate gave rise to rigors but arin did not Clotting was also retarded by storing od in containers with paraffin-lined walls But the ndard way of storing blood in Germany seems to be to x it with an equal volume of doubly distilled water taining 0 5% sodium citrate and 4% glucose Of od substitutes, physiological saline and a crystalloid ation named "tutofusin are stated to remain in the ulation for only 1–2 hours, but serum (fresh, stored or ed) and a colloid called "periston ' which is said to e no pharmacological properties remain in the ulation for 12 hours No hint of the composition of ofusin or periston is given Emphasis is laid on the ue of blood transfusion for conditions other than emia or hæmorrhage For example, numerous small nsfusions of stored blood are recommended in gas grene Immuno transfusion is used for sepsis, typhoid, diphtheria, influenza, erysipelas and typhus, and replacement transfusion—combined bleeding and transfusion—is recommended for acute toxæmia Schulz is dogmatic about the quantities to be used, more than 400–600 c cm should, he says, never be given at one time owing to the possibility of heart damage, which is more likely to occur if blood substitutes are used But for the hæmoconcentration of burns a blood substitute such as 30% glucose solution, periston or serum is preferred In the treatment of shock only 200–250 c cm of blood or substitute should be given, but for fluid replacement 400–600 c cm is allowed Such rigid standards, although they may serve to prevent over treatment by enthusiastic novices, cannot be in the interest of the patient It must surely be better to treat the patient according to the deficiency from which he is suffering, and the limits Schulz sets will then often be exceeded

CHILD ENDOWMENT

BY an act which came into force early this year a federal system of child endowment has been introduced in Australia From July 1 a payment of 5*s* per week will be made for each child under 16 years of age in families containing more than one child, and a similar allowance will be made to children in approved charitable institutions Normally the endowment will be paid to the mother and must be used for the child's "maintenance, training and advancement" It is estimated that about a million of the 1,830,000 children in Australia under the age of 16 belong to families with more than one dependent child so that the annual cost of the scheme is some £13 000 000 Two millions of this will be gained by abolishing income-tax abatements for each child after the first (so that the 5*s* will not in some cases be a clear gain) two millions from general revenue, and nine millions from the proceeds of a new pay-roll tax From the short account of this important legislation given in the *Ministry of Labour Gazette* for September, 1941, it appears that this tax is payable by all employers with a pay-roll of over £20 a week and is at the rate of 2½% on all wages, salaries, commissions, bonuses or allowances paid in money or kind The working of this scheme will be watched with interest in this country Meanwhile a similar but localised movement to ease the position of families with young children is reported from Birmingham Acting on the advice of its salaries wages and labour committee the city council has decided to give married employees 2*s* 6*d* a week for every child of school age, an innovation held to be more appropriate to wartime conditions, and fairer, than a general advance in wages for married and unmarried alike The alternative method now to be widely extended is to provide a good midday meal for all school-children This has the special advantage that it reaches not only necessitous children but also those whose mothers find it difficult, with or without endowment, to combine work of national importance in factories or elsewhere with the task of running a household Appliances, staff and suitable premises may be hard to come by, but such difficulties are not to stand in the way, one way or the other we shall bridge the slough of despond through which too many families with young children have had in the past to journey.

AT the Royal College of Surgeons of England on Tuesday, Nov 4 at 2 30 P.M., Mr L R Braithwaite will deliver a Moynihan lecture on the ileo-gastric syndrome Two Imperial Cancer Research Fund lectures will be given by Dr W E Gye F R S, director of the fund On Nov 6, at 3 30 P.M, he will speak on cancer of the breast, and on Nov 13, at 3 30 P.M., on filtrable tumours Dr A P Cawadias will deliver the Thomas Vicary lecture on Nov. 26, at 2.30 P.M. His subject will be hermaphroditism All these lectures will be held at 1 Wimpole Street, W 1, and doctors and students are invited to attend.

variation is well recognised by coaches An attack rarely disappears if the exertion is continued so that it has no relationship to second wind Cold weather seems to be a factor In a cross-country race run in a temperature of 15° F 40 out of 60 competitors had to give up because of stitch On another occasion one team "warmed up" outside in the severe cold and were able to finish the race, whereas their opponents warmed up indoors and all except one developed stitch Deep breathing usually increased the pain, bending over towards the side of the stitch, or pressure over the site, usually relieved it Capps suggests that the symptoms and the variability of the pain can be explained as being due to ischæmia of the diaphragm The relation of the pain to exertion, the compulsion to stop exertion, the relief on resting, and the precipitating effects of a full stomach and of cold resemble findings in angina pectoris and intermittent claudication, and give grounds for considering the ætiology of stitch alongside that of these proved ischæmic conditions That the pain is one sided can be explained by supposing that one side is affected first, thanks to the interruption of exercise the other side escapes The relief of the symptom by pressure over the painful spot or by bending towards the affected side could be explained by the consequent limitation of diaphragmatic movement Capps mentions the agonising stitch-like pain of uncontrollable laughter, laughter is associated with a series of rapid contractions of the diaphragm, and "laughter, holding both its sides" is certainly commoner after a large meal The theory that stitch is a referred pain from angina of the diaphragm to the intercostal nerves is a fascinating one, but the mechanism is as yet not definitely established Stitch in the shoulder might be expected on this hypothesis, but this was not observed though sought for Further evidence could be obtained by blocking the intercostal nerves involved in the supposed reflex, and possibly by observation of the diaphragm with X rays The theory must also be weighed in the balance of clinical observation

INTRASTERNAL TRANSFUSION

ANYONE with much experience of blood transfusion must have been baffled by patients with non existent veins, with veins which persist in becoming blocked (particularly where long and slow transfusions are required), with veins so collapsed or contracted in shock that they will not allow the transfusion fluid to pass, and by those cases in which every vein has already been used up This problem seems to have been solved by Tocantins and O'Neill,[1] whose preliminary tests have been most successful They found that saline solutions were absorbed rapidly from rabbits' bone-marrow and they adapted this finding to blood transfusion in man In adults the sternum is used, preferably the manubrium or midway between the angle and the xiphoid process In children under three years the upper end of the tibia or the lower end of the femur is preferred The technique is not difficult and can easily be mastered on the cadaver Tocantins and O'Neill use an instrument consisting of a gauge-15 needle housing an inner gauge-18 needle which in turn contains a stylet Three lengths are desirable—2, 3 5 and 5 cm—and once inserted the needle is prevented from penetrating more deeply by a collar held by a set screw The site chosen is first anæsthetised down to the periosteum with procaine, and the double needle is then pushed and twisted down to the periosteum at right angles to the skin Next the needle is tilted to about 30° with the skin and the anterior plate of the bone is perforated This is recognised by a lessened resistance The collar is then adjusted and the stylet removed A syringe containing about 1 c cm of saline is attached to the inner needle and gentle suction should bring some marrow into the syringe Not more than 0 5 c cm of marrow is a and the inner needle is removed and flushed out the saline and reinserted Saline is alternately inj and aspirated through it to displace air from the o needle Finally 1–2 c cm of saline is injected into marrow, the inner needle removed and rubber tub filled with saline leading from the reservoir is attac to the outer needle Speed is essential because marr clots easily At first the flow is only about 2–4 c c per minute but it quickens in about a quarter of an ho With a head of pressure of about 100 cm the rate of t in adults has been up to 25 c cm per minute and in t tibia or femur in children up to 4 2 c cm per min A successful infusion can only be given into a va bone-marrow and this will contain very little fat, so th the danger of fat embolism is said to be non ex Tocantins and O'Neill had no untoward reactions wi 52 infusions in 33 adults and 7 infants

EVERYBODY'S BUSINESS

IN the United States health education has long b valued as a tool by public health workers T recognise, as a recent report[1] from the American Pub Health Association shows, that even with adequa sanitation, immunisation and enforcement of laws, n community can achieve its highest possible standard of health unless it has been educated to the job To be wholly effective any programme would have to be universal, reaching every section of the public and taking into account both local and general public health requirements No such universal plan is yet available, but individual ventures are afoot in many states, and a committee was set up by the association to study some of these, this report gives arresting accounts of them Local programmes may have the drawbacks of paro chialism, but they also have its advantages, for, as th report says, "it is a sound, democratic, self relia procedure for a group of people, with the help of specia qualified leaders, to find their own health problems a to seek the needed information through which they c solve these problems" The committee studied health programmes in action in 26 communities in states Many of these communities had made great of the schools in their plan, judging that the ch influence on the parent was likely to be considera advertisers indeed have long guessed as much and o plan campaigns which reach the parent through t child Moreover, as the committee point out, the sch is the only social agency employing trained educa in the ratio of one to every forty people The u approach was to get the children first to observe make lists of the health needs of their community, t to analyse these in the classroom and study how s problems are being met elsewhere, and finally to plan solution of their local problems which would be with the means of the community

A campaign against hookworm in Bulloch Count Georgia is a good example of the method The zone c mittees of the schools learned through the state hea department that 60% of the school-children were infe with hookworm, in one school the figure being as h as 83% and in another as low as 13% Here was a c munal as well as a personal problem First the sch teachers had to be taught about hookworm and to t a test set by the health department, which also supp literature and films for the teachers to use later in classrooms Then the pupils studied the hookworm, life-history, the way it spreads, and how those inf can be treated They went home and told their pa about it, no doubt graphically Plans were then la for treating infested children and adults and for prev ing further soil pollution The schools, the health dep ment, the doctors, the parents of the children and t of the grown citizens were all persuaded to take part e campaign. By the spring of 1940 the incidence of worm in the schools had been reduced to 28% while pupils and teachers had been studying soil tion and had come to the conclusion that it could be prevented, in their county, by building sanitary privies Each child then made a report on the nce or absence of such a facility at his home , where privy existed he reported on its site and condition, in this way a map of sanitary conditions in the ity was compiled The schools then sponsored a ect for the construction of privies Members of the nt-Teacher Association gave the lumber, the health rtment provided the plans and chose the site, and r bodies were responsible for labour and transport of kers Between the autumn of 1936 and the spring 940 approximately 3500 privies were built

SOLUSEPTASINE SPRAYING IN THE PROPHYLAXIS AND TREATMENT OF COLDS*

W R THROWER, M D LOND , M R C P

THE application of various sprays and other solutions to the upper respiratory passages enjoys general popularity for its supposed effects on acute catarrhs, but no scientific evidence has ever been advanced which would justify the widespread adoption of any particular prophylactic or therapeutic measure of this kind Properly controlled research on " colds " is difficult to carry out on the scale necessary to produce results likely to bear statistical analysis Several large experiments have been conducted in the past to evaluate some of the more promising agents for controlling colds, such as vaccines, vitamins and ultraviolet light (Bashford 1938, Sherman 1938, Diehl et al 1938, Read 1939) The results, however, were disappointing

Among matters affecting health in crowded air-raid shelters the question of what to do about colds featured largely but no existing method of prophylaxis or treatment seemed sufficiently established for immediate application , yet something had to be done and done quickly Having in mind the usefulness of sulphonamides in controlling the secondary invaders of the common cold (Yates 1939, Elyan 1938, 1939), the feasibility of using these compounds was reviewed by the Horder Committee, for if even the unpleasant sequelæ of colds could be reduced it would be a distinct therapeutic advance The prophylactic use of sulphonamides by mouth is open to serious limitations under the best conditions, and their widespread use among shelterers would be hazardous There was some evidence that the course of common colds might be influenced by the application through an atomiser of a solution of disodium-*p*-(γ-phenyl-propyl-amino)benzenesulphonamide-α-γ-disulphonate, commonly called Soluseptasine, though a solution of this sulphanilamide derivative similar in all respects to that used for the present investigation in the form of nasal drops did not produce very striking results in a small-scale experiment (Dudley Hart 1941)

To apply a soluble sulphonamide in solution to an epithelium possessing the particular characteristics of that in the nose is a very different matter from placing sparingly soluble compounds into purulent wounds, concerning which opinion has been expressed elsewhere (Thrower 1940), or into carefully investigated wounds of the type described by Colebrook (1941)

Certain limitations are imposed by any field trial, and such weaknesses as may exist in the scheme finally adopted for shelters derive from the necessity of making the trial simple and capable of speedy completion Such simplification was more than justified in the light of experience gained by working and living among shelterers, and the practical limitations of similar surroundings on any such future trial should be remembered Unqualified census figures from individual shelters are misleading for various reasons The floating population of all shelters is high, owing to social visits and similar causes This irregularity can be lessened by the ticket system of entry Quiet nights are immediately reflected in poor attendances, and with an early " all clear " many naturally return home Arrival and departure times are variable, depending on such diverse factors as the closing times of public-houses and families waiting for treatment " until Dad comes from work " The mass exodus in the morning raises its own problems Ailments totally unconnected with the one being investigated are suggested as being due to the test, and this leads to defection in the control as well as in the treated group The idea that " they are doing something " about upper respiratory infections has considerable popular appeal, but the need for regularity, always important but doubly so in any trial, is unappreciated by the public at large Persuasion is the only approach possible, since there is not even the discipline o hospital outpatients or the health service of a undertaking Treatment at an entrance doorway impracticable, and plans for each shelter must be d on the spot Mass treatment at medical aid posts not work

As originally conceived, the trial was planned determine whether the routine spraying of nostrils w have any effect on the incidence of colds, but sepa records were made to determine whether treatm shortened the period of malaise and local discom Solutions of various compounds in different stren were tested privately on volunteers but all w abandoned for various reasons, with the exception 10% solution of soluseptasine in water containing w/v glycerin to lower surface tension For control group the solution used was normal salin

One basement-type shelter was selected for trea cases, and one in an adjacent London borough for con cases, no-one knowing the nature of the solutions u The general conditions in these shelters were compar in that they were in the basements of modern flats a housed people of similar social type The ave nightly population during November, 1940, was appr mately 250 in each shelter, but the numbers dec with quieter nights, to rise again with more aerial acti different people, however, often taking the place the former occupants The general decline in all shel populations, apart from staffing difficulties, made t obtaining of reliable statistics in immediate furthe trials of this nature so unlikely, except under unmanageable conditions, that two tube stations were chosen for further trials, as probable sources of quick results A tube station of simple design was selected, the up platform being used for treated cases and the down platform serving as control The net numbers treated here agai reflect the problem of the floating population and defec tions As a control against the first station, anothe one was used, but the results proved worthless f statistical assay owing to sociological difficulties Th results obtained in basement shelters cannot be compar with those obtained from tube stations owing to t entirely different nature of the surroundings

TECHNIQUE AND RESULTS

A mixed group of men, women and children we sprayed in each nostril with the appropriate sol night and morning with three puffs from an ordi nasal atomiser, the total quantity used being kep constant as possible at about 0 6 c cm (i e 60 soluseptasine)

For the guidance of other workers a few prac points are worth recording To those who are laryngologists it is remarkable what a wide vari there is in the size, shape and direction of the na passages possessed by an unselected crowd of pe Some practice is needed with individual cases to be that the atomised solution comes into wide inti contact with the nasal mucosa In ordinary pra among patients who may have to treat themselves it be important to ensure that this proper applicatio effected Constant use of atomisers shows how and unreliable many of them are Metal nozzles essential so that quick sterilisation in a flame is po when numbers of patients have to be treated In large-scale treatments constant supervision by a me man is necessary in the early stages, not only to rea the public but also to train nurses or other helpers in requisite technique

No epistaxis or signs of general toxicity occurred either group Subjects in both the treated and co groups, particularly the former, remarked that t tended to have wetter noses than normally, and m some pronounced cases of this wetness have been reco as colds on single occasions when diagnosis by a qua person was not possible , these doubtful cases have excluded from both groups before the assessment results There were no complaints of nasal conge or obstruction, while chance sampling with a n speculum revealed no abnormalities Some subj with colds in both groups claimed relief of sympt immediately after the spraying

A log was kept showing the occasions on which were sprayed night and morning, and recording the ation of colds, including those already in existence he trial commenced, the first 36 hours of these xcluded People who said that they were suffer- n a cold often claimed relief in 12 hours (when the cord was made), but these " colds," as mentioned have been excluded from the total figures The erage period of observation despite the large rs treated is due to the chronic absenteeism, while who received less than seven days' treatment have xcluded

---

* Based on the report of an investigation carried out on behalf of the Horder Committee on Health Conditions in Air raid Shelters (Ministry of Home Security and Ministry of Health)

hylaxis—In the basement shelters 57 treated s were observed for an average of 1 5 weeks, and %) had colds Of 70 controls observed for an e of 2 weeks, 39 (55%) had colds In the tube is 115 persons were observed for an average of 2 8 , and 12 (10 4%) had colds Of 90 controls ed for an average of 2 5 weeks, 18 (20%) had colds will be seen that in the basements there were rtionately more colds in the treated than in the l subjects, whereas in the tubes the reverse applied ariations in both cases were greater than could plained by mere chance, but I cannot put forward ther explanation Both basement shelters had mics of colds during the experiment

atment—In the basement shelters the average ion of colds has been roughly assessed from the cols as 60 hours in the treated and 199 hours in ontrol group In the tube stations the average ion was 28 9 hours in the treated and 49 8 hours in ntrols

difference in duration of the colds in the two types elter may have been due to the better ventilation reater space per person in the tubes, or it may, of e have been due to greater virulence of the organism icing the epidemic colds in the basements No clinical pathology was possible, so that the nature of the colds could not be determined

CONCLUSIONS

In the small controlled experiment completed no case was made out either for or against the prophylactic spraying of nostrils with a solution of soluseptasine The practical limitations to success in such a procedure suggest that no useful purpose would be served by continuing this in the shelters at present The basis is admittedly small, but the figures do suggest a reduction in the average duration of colds in both the treated groups compared with the controls This confirms the clinical impression concerning soluseptasine which justified the trial being carried out, and a repetition of the work is desirable on people living in closed communities suffering from colds, using the technique developed during the present investigation Observations in connexion with general hygiene which must affect the incidence of upper respiratory catarrhs were outside the scope of the experiment

Credit for the expedition of the trial is due to Dr G H Oates and Dr H A Bulman, medical officers of health, and my thanks are due to the scientific staff of Messrs May and Baker Ltd for technical assistance, and to Mr Bradford Hill, D Sc , for checking the results

MEDICINE AND THE LAW

Damages against Chiropodist

Colston *v* Frape, a recent case at the Barnstaple ty court, a woman recovered £62 15*s* damages with for injury to her foot She had visited a chiropo- or treatment of her corns , he advised her that her required treatment When she paid a second visit is purpose he took hold of her foot with both hands twisted and jerked it with some force Such was vidence, and she complained that, in consequence e wrench, she suffered pain and could not now walk ell as formerly The defendant, who described elf as a chiropodist and specialist in the fitting of , said that he formed the opinion that the plaintiff suffering from some form of pressure on the nerves , enied wrenching her foot or inflicting worse pain she was already experiencing He had manipulated oot in order to " free the nerves and strictures ", dmitted that this might have caused some local gnation " to flare up The judge held that the podist, though neither responsible for the original ition of the foot nor negligent or unskilful in his ment, had been at fault in his diagnosis or advice did not know what was wrong, he ought to have ed the plaintiff to see a doctor The court awarded ges for the injury due to the wrong treatment being nistered after the primary injury had occurred judge did not fail to point out that the plaintiff had tarily submitted to the treatment and knew quite that the chiropodist was not a surgeon We have l in these columns other cases where a patient's in an unqualified practitioner has been inadequately rded The Medical Act set up a Register because, preamble declares, it was ' expedient that persons ring medical aid should be enabled to distinguish fied from unqualified practitioners " This is no ntage to patients who prefer to get their manipula- surgery from a chiropodist

Professional Monopoly

spite of such cases the uninstructed public will theless continue to speak as though registered practi- rs possessed a monopoly of practice in surgery and cine If one wants to see a true professional poly at work, one should turn to the legal pro- on Penalties await any unqualified person who dares to " act as a solicitor " or sue out any writ or process as such or begin or defend any legal proceeding in the name of any other person or who, " for or in expectation of any fee, gain or reward," draws or prepares a will or other legal document The new Solicitors Bill, which has passed through Parliament with an ease the more surprising because its clauses have no intimate connexion with the national war effort fortifies an already formidable organisation An unauthorised person will have the onus of proving that he did not act for or in expectation of a fee Every solicitor will have to join the Law Society, though this requirement will not operate until a poll of all practising solicitors has shown a two-thirds majority in its favour Another interesting feature is the creation of a compensation fund to relieve the losses suffered by members of the public through acts of dishonesty or breaches of trust committed by solicitors or their clerks To this fund every solicitor will have to make a fixed annual contribution not exceeding five pounds Shall we yet see all registered medical practitioners compelled by law to contribute to a pool for guaranteeing patients against the consequences of professional negligence ?

E M S Surgeon's Libel Action

One of the surgeons appointed by the Ministry of Health to deal with war and air-raid casualties under the Emergency Medical Service had occasion recently to claim damages for defamatory statements suggesting that he had been inconsiderate, incompetent and negligent in the exercise of his professional duties The plaintiff was Mr G H Lawson Whale, F R C S , who had been appointed to the Hampstead General Hospital After an air-raid on Hampstead a year ago a mother and two daughters attended at the hospital One of them was discharged at once , another had a hæmatoma near her mouth and the medical practitioner who attended to her asked Mr Whale's opinion about tracheotomy After making an examination Mr Whale advised that the operation was unnecessary Three weeks later Mr Thomas Sargant, in whose house the three women lived addressed to the secretary of the hospital a letter complaining that the surgeon who attended to them was " callous and brutal in his attitude to them "; he was " chiefly concerned to get them out of hospital as soon as possible ", he " succeeded in his harsh manner in reducing all the patients to tears ' Later Mr Sargant wrote that the surgeon in question was Mr Lawson Whale Mr Whale naturally took action upon these damaging statements As his counsel explained, he did not seek punitive damages but merely asked for a verdict which would discourage such allegations as Mr Sargant made The three women were not Mr Whale's patients , it was no part of his duty to interfere in their treatment unless invited to do so Mr Sargant had been told that he was misinformed , he had, however, refused to accept the statement Mr Whale denied in the witness-box that the hospital was conducted in the spirit of getting rid of patients as quickly as possible Mr Justice Atkinson asked if the Ministry of Health had issued any instruction for turning patients out on a war-time rather than a peace-time standard Mr Whale replied that he had always found it easy to keep patients there as long as he would have done in normal times The hospital staff had been warned to regard themselves as a casualty clearing station rather than as a base hospital , actually they had found it possible at all times to act as a base hospital Mr Arthur Gray, F R C O G , a colleague at the hospital, expressed the opinion that the three women were not in fact suffering from shock

Mr Sargant gave evidence on the second day of the hearing and explained his motives His original letter had said that he made his protest as a ratepayer , in his written defence he had pleaded that the occasion was privileged inasmuch as he addressed the hospital as a citizen, taxpayer and ratepayer of Hampstead, in good faith and without malice, under a sense of duty to someone who had a corresponding duty in the matter and in the honest belief that the contents of his protest were true If the occasion were privileged Mr Whale would not succeed unless he could prove malice Having heard Mr Sargant's evidence, Mr Whale felt satisfied that the defendant had acted in good faith He himself had been concerned merely to protect his reputation against what seemed the malicious attack of a busybody He was now prepared to withdraw the action and pay the defendant's costs , Mr Sargant on his side acknowledged that his letter had been too strong and expressed his regrets The judge approved the settlement In his view the occasion of the letter was undoubtedly privileged It was important, he observed, that it should be made clear that there had been no plea of justification , Mr Whale's course of action implied no admission that complaint was well founded So long as there was no reflection upon Mr Whale, his lordship was satisfied with the result , he did not wish it to be thought that this termination of the case reflected upon the plaintiff in any way

SCOTLAND

THE SCOTS HOSPITAL PROBLEM

ON Oct 14 the Secretary of State for Scotland, replying in the House of Commons to a question on hospital policy, said that he was having consultations with the bodies concerned and could not at that stage add anything to the general statement made by the Minister of Health The bodies concerned are presumably the voluntary hospitals, the local authorities and the Nuffield committee The Minister of Health in his general statement foreshadowed some special measures applicable to Scotland in the formulation of hospital policy, and doubtless these special measures will be under discussion at the meeting to which Mr Johnston referred The difference between the hospital problem in Scotland and that in England is essentially one of degree Scotland, as is well known and as was brought out in the report of the Committee on Scottish Health Services, is not nearly so well provided with hospital beds as is England If, as Mr Johnston said in opening the Ayrshire Central Hospital recently, it is the aim of the Government in their plans for the post-war hospital service to ensure that proper treatment is available to every person in need of it, the question of adequate provision in Scotland is one that is bound to be compelling It is probably true, as the Secretary of State said at Ayr, that there are large numbers of people suffering unnecessary pain or discomfort, unable to pull their full weight, the condition of many of them deteriorating He wants to remove that reproach to our hospital system, and he wants to develop the hospital service in the form of a kind of partnership amongst the various hospital authorities, and especially to see the greatest possible cooperation between tary hospitals and local authorities, so that every may fill the roll best fitted to it in a coordinated on a regional basis The Secretary of State de implication, to retain the voluntary hospitals doubtless he must be giving serious thought as t best method of giving necessary state aid to t whether through the agency of local authorities c He must be concerned, too, to know how best to the ad-hoc hospitals erected under the auspices c department and directly administered by it hospitals were primarily designed to fill gaps i treatment of war casualties, but it would be prepo to allow them to fall into disuse when the war b though there may be a strong Treasury urge in direction It seems probable that these hospital have to be retained as important entities in a coord service involving local authorities, voluntary ho and the Department of Health Whether the last will wish to continue to administer these ho directly is one of the intriguing but comparatively problems that beset the Secretary of State

HEALTH OF EIRE

THE report of the department of local governme public health for the year ended March 31, 1940, r a decline in the incidence and mortality of the pri infectious diseases, in infant mortality and in mat mortality The number of notifications of infect diseases—6116—was the lowest since 1930, and ab 1900 fewer than in 1938 This reduction was m due to a fall in the incidence of scarlatina and of dip theria, the latter probably due to the campaign preventive immunisation carried out in recent years the county medical officers of health Yet there w still 2097 cases of diphtheria with 245 deaths and 2 cases of scarlet fever with 43 deaths Compared the previous year, typhoid notifications had risen fr 254 to 385 and the number of deaths from that dis from 46 to 56 Many of the cases were traced to ca In a local epidemic in co Kerry, with 103 cases deaths, infection was spread by separated milk creamery The milk was apparently infected by a of typhoid in one of the farms supplying the mil the creamery the cream was pasteurised and co into butter, but the separated milk was sold unt In most of the cases there was definite evidence th separated milk had been consumed by the patie case was traced to the butter, There were only a of typhus, with 3 deaths, and this disease seems gradually disappearing Only 76 cases of pu sepsis were notified, the smallest number for many the number of deaths from this cause was 38, the l on record

The infant mortality-rate was 66 per 1000 l which is lower than that for Northern Ireland (Scotland (69), but higher than that for Engla Wales (50) Congenital debility heads the list causes of infant mortality, premature birth second and diarrhoea and enteritis third The in death-rate in urban areas was 83 per 1000 b 90 in Dublin—and the rate for rural areas w Mortality from tuberculosis had increased—1 1 1000 of the population as against 1 09 in the p year But these are the two lowest figures ever re There are no trustworthy statistics to show th dence of the disease, as notification is only ma where the sputum or other infective discharge i to spread infection This useless order dates b 1919 and has always hampered the campaign a tuberculosis Nevertheless, owing to the great which was made to assure notification and cert it is probable that the increase was not real medical officer of Cavan said "The generation growing up has little or no conception of the u dread of this plague which prevailed when the car against tuberculosis was initiated thirty year Most of the medical officers of Eire have worked t overcome this dread, which lived in Ireland long a had died elsewhere, and because of their efforts and growing enlightenment of the people concealm tuberculosis is gradually passing, but it is still pr especially in the west In 1939 135,404 school were examined Dental defects w erved in se of the tonsils or throat in 19 1% Treatment onditions is provided free where necessary dministration of the Milk and Dairies Act by authorities has been on the whole satisfactory proceedings for non-compliance with statutory ents have been successfully instituted though ort adds that some local authorities were to take action on the recommendations of dical and veterinary advisers This seems to te the case, for many local authorities fail to te the importance of the act and are unwilling cute negligent milk-producers while the local fail to impose adequate penalties in the cases before them

g the year 952 936 new cases were attended by dispensing medical officers It seems therefore out a quarter of the population of Eire received attendance under the Medical Charities Act. ome of the Hospitals Trust Fund for 1939 was 202 600, and the expenditure £367 800 Grants 384 were made to poor-law and county hospitals, 9 822 to voluntary hospitals of which £126,072 neet current expenses

ARGENTINA

AVIATION

VICE of air ambulances for both official and private been established under the control of the national ment of health When used for private patients rge is 50 centavos a kilometre Three machines manently attached to this service in the sparsely ed regions of the Chaco and the southern terri- Analysis of the effects of aviation on both and sick people has led Prof M R Castex and his ies to conclude that of the cardiac and circulatory rs only cases of myocardial degeneration can safely ned by air, and that patients with respiratory ns other than bronchitis or chronic pleural disorders n-exudative nature should also avoid flying

planned to establish a division for the sanitary ision of aircraft in the department of health, with to checking the spread of infection by aircraft g from infected regions. Aviation is on the e in the Argentine In 1938 there landed in Aires 770 aircraft carrying 7300 passengers s in 1940 the figures were 1800 aircraft and 15 800 gers Aircraft may carry infected insects but s also the risk that passengers may still be in the tion period of an infectious disease when they and so will not appear ill

BREAST-MILK CENTRE

government has established a non-profit-making in Buenos Aires for extracting preserving and uting surplus breast milk The old mothers'-milk is were mainly based on the wet-nurse system. but ntre obtains its milk from normal mothers, and it nd possible to take 200–300 grammes from many rs without depriving their own children The s' family histories are inquired into, and they go a periodic clinical radiological and serological nation During 1940 over 5000 litres of milk were ed to 1200 babies from 350 donors The price ed ranged from 7s a litre down to nothing according means of the recipient, more than half of the milk upplied gratuitously

PSITTACOSIS

ing the pandemic of 1929–30 which involved s Aires and part of northern Argentina about ises of psittacosis were reported Then in the next ears there were only isolated cases but in 1939 an ak in Buenos Aires produced 27 cases of which %) died The disease mainly attacks adults of and hardly ever children Men and women are d equally, and bird-dealers are, as might be sup- the commonest sufferers Cold weather seems our the propagation of the disease, and the incuba- period is 7–14 days During this last epidemic rrhagic skin lesions have been observed No ent has been of any avail

HEART DISEASE

10 000 school children examined in Buenos Aires had organic heart disease, 2% being acquired and the remainder congenital It is hoped that early recognition of cardiac lesions will improve the prognosis. for Prof Rafael Bullrich estimates that the mortality from cardio-articular rheumatism is at present as high if not higher in the Argentine than in any other country and a speaker in the Senate said that 2 4% of Argentine children under 14 die from the disease According to Macera and Costa Bertani the fatality from acute rheumatism in children under 15 is 22% in Buenos Aires and 12 5% in Rosario

Professor Bullrich has also made a clinical and statistical study of people over 60, and in the last ten years he finds that circulatory diseases accounted for 43% of the deaths between 60 and 80 ; if nephritis is included (and nearly all cases in this age-group are circulatory in origin) the figure rises to 47% Since 540 000 of the 13½ million population of the Argentine are over 60 the social significance of these diseases is clear The number of hospital beds for such cases is insufficient but much may be hoped from the work of the Institution for Social Assistance to the Cardiac of which Professor Bullrich is director This institution, which is a voluntary one and has been running for three years undertakes the care of pregnant women nursing mothers and children with cardiac lesions promotes the organisation and equipment of dispensaries and colonies for their treatment and puts forward legislation on behalf of workpeople with heart disease At a congress of the institution recently held in Buenos Aires it was urged that clinics for heart disease should be established in the Argentine such as already exist in Britain and the U S A Dr Luis Sabathie who has lately published an extensive monograph on the subject emphasised the inadequacy of purely medical methods in treatment One remarkable statement made by subsequent speakers was that 70% of anarchists and other revolutionaries suffer from some physical disability which prevents them from following a normal calling

---

WOMEN CONFER ON INDUSTRY

THE second session of the London Women's Parliament held on Oct 27 at the Conway Hall was attended by 371 delegates representing 211 groups which included coöperative organisations guilds trades unions discussion groups and education committees Mrs NAN McMILLAN recently president of the National Union of Women Teachers took the chair

Miss MARY CORSELLIS, the organiser was able to inform the meeting of the results of the first session Improvements had been reported from factories to which the L W.P had sent delegates The Parliament had been recognised by the Minister of Labour suggestions on milk rationing and the differential distribution of oranges had been adopted An investigation of conditions in factories had been carried out and an inquiry into the provision of day nurseries and into school feeding was foreshadowed

Discussion at the second session ranged over a bill to regulate supplies and distribution of food and a series of proposals designed to remove the obstacles now preventing women from playing their full part in industrial production

The speakers were lucid and brisk, much more concerned with facts than theories Among them were councillors, teachers, transport workers ambulance drivers clerks, housewives nursery school supervisors. canteen managers and workers from clothing, munition and aircraft factories They had many abuses to point out but there was a striking growth, during the meeting of the conviction that it was not by individual and intermittent grumbling that these could be remedied but by the deliberate and combined action of the women doing the jobs The factors held to be largely responsible for keeping women from keen participation in the work of production were low wages insufficient day nurseries long working hours and consequent shopping difficulties bad canteens and inadequate transport

WAGES AND WORK

Of these perhaps low wages received least attention in the discussion although the hardship caused by this factor is sometimes great Some girls under 20 are unable to earn a wage on which they can get enough to eat In most factories women are paid much lower wrote that the surgeon in question was Mr Lawson Whale Mr Whale naturally took action upon these damaging statements As his counsel explained, he did not seek punitive damages but merely asked for a verdict which would discourage such allegations as Mr Sargant made The three women were not Mr Whale's patients, it was no part of his duty to interfere in their treatment unless invited to do so Mr Sargant had been told that he was misinformed, he had, however, refused to accept the statement Mr Whale denied in the witness-box that the hospital was conducted in the spirit of getting rid of patients as quickly as possible Mr Justice Atkinson asked if the Ministry of Health had issued any instruction for turning patients out on a war-time rather than a peace-time standard Mr Whale replied that he had always found it easy to keep patients there as long as he would have done in normal times The hospital staff had been warned to regard themselves as a casualty clearing station rather than as a base hospital, actually they had found it possible at all times to act as a base hospital Mr Arthur Gray, F R C O G, a colleague at the hospital, expressed the opinion that the three women were not in fact suffering from shock

Mr Sargant gave evidence on the second day of the hearing and explained his motives His original letter had said that he made his protest as a ratepayer, in his written defence he had pleaded that the occasion was privileged inasmuch as he addressed the hospital as a citizen, taxpayer and ratepayer of Hampstead, in good faith and without malice, under a sense of duty to someone who had a corresponding duty in the matter and in the honest belief that the contents of his protest were true If the occasion were privileged Mr Whale would not succeed unless he could prove malice Having heard Mr Sargant's evidence, Mr Whale felt satisfied that the defendant had acted in good faith He himself had been concerned merely to protect his reputation against what seemed the malicious attack of a busybody He was now prepared to withdraw the action and pay the defendant's costs, Mr Sargant on his side acknowledged that his letter had been too strong and expressed his regrets The judge approved the settlement In his view the occasion of the letter was undoubtedly privileged It was important, he observed, that it should be made clear that there had been no plea of justification, Mr Whale's course of action implied no admission that complaint was well founded So long as there was no reflection upon Mr Whale, his lordship was satisfied with the result, he did not wish it to be thought that this termination of the case reflected upon the plaintiff in any way

SCOTLAND

THE SCOTS HOSPITAL PROBLEM

ON Oct 14 the Secretary of State for Scotland, replying in the House of Commons to a question on hospital policy, said that he was having consultations with the bodies concerned and could not at that stage add anything to the general statement made by the Minister of Health The bodies concerned are presumably the voluntary hospitals, the local authorities and the Nuffield committee The Minister of Health in his general statement foreshadowed some special measures applicable to Scotland in the formulation of hospital policy, and doubtless these special measures will be under discussion at the meeting to which Mr Johnston referred The difference between the hospital problem in Scotland and that in England is essentially one of degree Scotland, as is well known and as was brought out in the report of the Committee on Scottish Health Services, is not nearly so well provided with hospital beds as is England If, as Mr Johnston said in opening the Ayrshire Central Hospital recently, it is the aim of the Government in their plans for the post-war hospital service to ensure that proper treatment is available to every person in need of it, the question of adequate provision in Scotland is one that is bound to be compelling It is probably true, as the Secretary of State said at Ayr, that there are large numbers of people suffering unnecessary pain or discomfort, unable to pull their full weight, the condition of many of them deteriorating He wants to remove that reproach to our hospital system, and he wants to develop the hospital service in the form of a kind of partnership amongst the various hospital authorities, and especially to see the greatest possible cooperation between voluntary hospitals and local authorities, so that every hospital may fill the roll best fitted to it in a coordinated scheme on a regional basis The Secretary of State desires, by implication, to retain the voluntary hospitals, and doubtless he must be giving serious thought as to the best method of giving necessary state aid to them—whether through the agency of local authorities or not He must be concerned, too, to know how best to utilise the ad-hoc hospitals erected under the auspices of his department and directly administered by it These hospitals were primarily designed to fill gaps in the treatment of war casualties, but it would be preposterous to allow them to fall into disuse when the war is over, though there may be a strong Treasury urge in that direction It seems probable that these hospitals will have to be retained as important entities in a coordinated service involving local authorities voluntary hospitals and the Department of Health Whether the last named will wish to continue to administer these hospitals directly is one of the intriguing but comparatively minor problems that beset the Secretary of State

HEALTH OF EIRE

THE report of the department of local government and public health for the year ended March 31, 1940, records a decline in the incidence and mortality of the principal infectious diseases, in infant mortality and in maternal mortality The number of notifications of infectious diseases—6116—was the lowest since 1930, and about 1900 fewer than in 1938 This reduction was mainly due to a fall in the incidence of scarlatina and of diphtheria, the latter probably due to the campaign of preventive immunisation carried out in recent years by the county medical officers of health Yet there were still 2097 cases of diphtheria with 245 deaths and 2779 cases of scarlet fever with 43 deaths Compared with the previous year, typhoid notifications had risen from 254 to 385 and the number of deaths from that disease from 46 to 56 Many of the cases were traced to carriers In a local epidemic in co Kerry, with 103 cases and 8 deaths, infection was spread by separated milk from a creamery The milk was apparently infected by a case of typhoid in one of the farms supplying the milk In the creamery the cream was pasteurised and converted into butter, but the separated milk was sold untreated In most of the cases there was definite evidence that the separated milk had been consumed by the patient, no case was traced to the butter There were only 5 cases of typhus, with 3 deaths, and this disease seems to be gradually disappearing Only 76 cases of puerperal sepsis were notified, the smallest number for many years, the number of deaths from this cause was 38, the lowest on record

The infant mortality-rate was 66 per 1000 births, which is lower than that for Northern Ireland (70) or Scotland (69), but higher than that for England and Wales (50) Congenital debility heads the list of the causes of infant mortality, premature birth comes second and diarrhœa and enteritis third The infantile death-rate in urban areas was 83 per 1000 births—90 in Dublin—and the rate for rural areas was 55 *Mortality from tuberculosis had increased*—1 13 per 1000 of the population as against 1 09 in the previous year But these are the two lowest figures ever recorded There are no trustworthy statistics to show the incidence of the disease, as notification is only mandatory where the sputum or other infective discharge is liable to spread infection This useless order, dates back to 1919 and has always hampered the campaign against tuberculosis Nevertheless, owing to the great effort which was made to assure notification and certification it is probable that the increase was not real The medical officer of Cavan said "The generation now growing up has little or no conception of the universal dread of this plague which prevailed when the campaign against tuberculosis was initiated thirty years ago" Most of the medical officers of Eire have worked hard to overcome this dread, which lived in Ireland long after it had died elsewhere, and because of their efforts and the growing enlightenment of the people concealment of tuberculosis is gradually passing, but it is still prevalent, especially in the west In 1939 135,404 school-children were examined Dental defects were observed in 46 6%, l disease of the tonsils or throat in 19 1% Treatment these conditions is provided free where necessary

Che administration of the Milk and Dairies Act by local authorities has been on the whole satisfactory, d legal proceedings for non-compliance with statutory quirements have been successfully instituted, though e report adds that some local authorities were uctant to take action on the recommendations of eir medical and veterinary advisers This seems to derstate the case, for many local authorities fail to preciate the importance of the act and are unwilling prosecute negligent milk-producers while the local stices fail to impose adequate penalties in the cases ought before them

During the year 952,936 new cases were attended by e 646 dispensing medical officers It seems, therefore, at about a quarter of the population of Eire received edical attendance under the Medical Charities Act ie income of the Hospitals Trust Fund for 1939 was er £1,202,600, and the expenditure £367,800 Grants £270 384 were made to poor-law and county hospitals, id £209,822 to voluntary hospitals, of which £126,072 as to meet current expenses

---

ARGENTINA

AVIATION

A SERVICE of air ambulances for both official and private se has been established under the control of the national epartment of health When used for private patients he charge is 50 centavos a kilometre Three machines re permanently attached to this service in the sparsely opulated regions of the Chaco and the southern territories Analysis of the effects of aviation on both ealthy and sick people has led Prof M R Castex and his olleagues to conclude that of the cardiac and circulatory isorders only cases of myocardial degeneration can safely e carried by air, and that patients with respiratory ffections other than bronchitis or chronic pleural disorders f a non-exudative nature should also avoid flying

It is planned to establish a division for the sanitary supervision of aircraft in the department of health, with a view to checking the spread of infection by aircraft arriving from infected regions Aviation is on the ncrease in the Argentine In 1938 there landed in Buenos Aires 770 aircraft carrying 7300 passengers whereas in 1940 the figures were 1800 aircraft and 15 800 passengers Aircraft may carry infected insects, but there is also the risk that passengers may still be in the incubation period of an infectious disease when they arrive and so will not appear ill

BREAST-MILK CENTRE

The government has established a non-profit-making centre in Buenos Aires for extracting, preserving and distributing surplus breast milk The old mothers'-milk stations were mainly based on the wet-nurse system but this centre obtains its milk from normal mothers, and it is found possible to take 200–300 grammes from many mothers without depriving their own children The donors' family histories are inquired into, and they undergo a periodic clinical, radiological and serological examination During 1940 over 5000 litres of milk were supplied to 1200 babies from 350 donors The price charged ranged from 7*s* a litre down to nothing according to the means of the recipient, more than half of the milk was supplied gratuitously

PSITTACOSIS

During the pandemic of 1929–30, which involved Buenos Aires and part of northern Argentina, about 200 cases of psittacosis were reported Then in the next nine years there were only isolated cases, but in 1939 an outbreak in Buenos Aires produced 27 cases of which 13 (48%) died The disease mainly attacks adults of 45–55 and hardly ever children Men and women are affected equally, and bird-dealers are, as might be supposed, the commonest sufferers Cold weather seems to favour the propagation of the disease, and the incubation period is 7–14 days During this last epidemic hæmorrhagic skin lesions have been observed No treatment has been of any avail

HEART DISEASE

Of 10 000 school-children examined in Buenos Aires 4% had organic heart disease, 2% being acquired and the remainder congenital It is hoped that early recognition of cardiac lesions will improve the prognosis, for Prof Rafael Bullrich estimates that the mortality from cardio-articular rheumatism is at present as high if not higher in the Argentine than in any other country and a speaker in the Senate said that 2 4% of Argentine children under 14 die from the disease According to Macera and Costa Bertani the fatality from acute rheumatism in children under 15 is 22% in Buenos Aires and 12 5% in Rosario

Professor Bullrich has also made a clinical and statistical study of people over 60, and in the last ten years he finds that circulatory diseases accounted for 43% of the deaths between 60 and 80 if nephritis is included (and nearly all cases in this age-group are circulatory in origin) the figure rises to 47% Since 540 000 of the 13½ million population of the Argentine are over 60 the social significance of these diseases is clear The number of hospital beds for such cases is insufficient but much may be hoped from the work of the Institution for Social Assistance to the Cardiac of which Professor Bullrich is director This institution, which is a voluntary one and has been running for three years undertakes the care of pregnant women, nursing mothers and children with cardiac lesions, promotes the organisation and equipment of dispensaries and colonies for their treatment and puts forward legislation on behalf of work-people with heart disease At a congress of the institution recently held in Buenos Aires it was urged that clinics for heart disease should be established in the Argentine such as already exist in Britain and the U S A Dr Luis Sabathie, who has lately published an extensive monograph on the subject, emphasised the inadequacy of purely medical methods in treatment One remarkable statement made by subsequent speakers was that 70% of anarchists and other revolutionaries suffer from some physical disability which prevents them from following a normal calling

---

WOMEN CONFER ON INDUSTRY

THE second session of the London Women's Parliament held on Oct 27 at the Conway Hall was attended by 371 delegates representing 211 groups which included cooperative organisations guilds trades unions discussion groups and education committees Mrs NAN MCMILLAN, recently president of the National Union of Women Teachers, took the chair

Miss MARY CORSELLIS, the organiser, was able to inform the meeting of the results of the first session Improvements had been reported from factories to which the L W P had sent delegates The Parliament had been recognised by the Minister of Labour, suggestions on milk rationing and the differential distribution of oranges had been adopted An investigation of conditions in factories had been carried out and an inquiry into the provision of day nurseries and into school feeding was foreshadowed

Discussion at the second session ranged over a bill to regulate supplies and distribution of food, and a series of proposals designed to remove the obstacles now preventing women from playing their full part in industrial production

The speakers were lucid and brisk, much more concerned with facts than theories Among them were councillors, teachers, transport workers ambulance drivers, clerks, housewives, nursery school supervisors, canteen managers and workers from clothing, munition and aircraft factories They had many abuses to point out, but there was a striking growth, during the meeting, of the conviction that it was not by individual and intermittent grumbling that these could be remedied but by the deliberate and combined action of the women doing the jobs The factors held to be largely responsible for keeping women from keen participation in the work of production were low wages, insufficient day nurseries, long working hours and consequent shopping difficulties, bad canteens and inadequate transport

WAGES AND WORK

Of these perhaps low wages received least attention in the discussion, although the hardship caused by this factor is sometimes great Some girls under 20 are unable to earn a wage on which they can get enough to eat In most factories women are paid much lower wages than men , thus inquiries made by the organising committee in a large number of factories showed that a woman in engineering now earns a minimum of 38*s* In Government training centres this is the starting wage, and after three tests she gets 47*s* , a man earns 22*s* 6*d* more throughout the training course When a woman leaves the centre and starts work in a factory she drops back to 38*s* plus a bonus for piece work , but in explosive factories many processes are too dangerous for piece work The average earnings for an adult woman in engineering today are below £2 10*s* (equivalent to 39*s* before the war) When she has paid for food, lodging and transport she may find herself only a few shillings in pocket at the end of the week If she has to contribute to the care of her children, or send money home to her family she may have less than enough for food National Service officers have been obliged in some cases to release a woman from nationally important work on the ground that the pay did not enable her to support herself This is made worse by the fact, which came out clearly in discussion, that many women, though trained for and capable of skilled work, are being used in factories as cheap labour to do routine jobs which could be entrusted to a newcomer, and are thus being prevented from earning higher rates of pay

Miss G **Rowland**, speaking of the large engineering factory at which she works, said there was no collaboration between the Government training centres and the factories Women trained as toolmakers would go to the factories and be set to work on some other task She estimated that 50% of women fail to get employment in the job for which they have been trained , and recently workers at her factory had decided to arrange a small conference between delegates from the factory and instructors from the centres to discuss better collaboration in the district Miss **Norah Brown**, a member of the organising committee of the L W P , pointed out that there had been a 33% increase in fatal accidents in factories in the past year Some of these are doubtless the outcome of fatigue due to long hours—a ten-hour day and a 56-hour week is common—some to lack of training , but an increase in legal penalties for such accidents, she thought, showed that the management had been responsible for some

FOOD AND SHOPPING

The hours worked make shopping problems serious for women Mrs **Hanson**, a transport worker, said that in Birmingham women employed in the factories only had Saturday afternoon on which to do all the buying-in for the week , the shops were then so crowded that many of them could not even buy their rations The city council, when approached, said that this was a national problem, and that they could do nothing until some national plan had been devised In Finchley it seems they are more progressive , there, Councillor Mrs **Diana Pym** said, the food committee has organised passes for women workers so that they can get their proper share of goods in the shops She suggested that shops might arrange to stay open later on one night a week The problem of shopping would of course be much eased if there was more provision for communal feeding and for school meals for children The topic of school meals was very close to the heart of the meeting Mrs **Mary Marston** pointed out that they were especially necessary where the mother went out early to work at the factory , she dared not leave the children alone in the house with a fire burning, so she usually brought them along to school They hung about, turning somersaults on the railings and getting rather cold, until school opened, and then had nothing to look forward to at lunch-time except a sandwich of doubtful ingredients—and " no little bit of pudding " Other speakers agreed in disparaging such " nosebag meals," and all felt that the Government should be pressed to carry out its promise of universal school feeding

The lack of day nurseries, however, was felt to be the paramount factor keeping women out of industry at present Mrs **Carter**, of the Society for the Provision of Nursery Schools and Day Nurseries, said that local authorities had the power to set up nurseries but many of them had not done so They thought that mothers could always find a neighbour to look after children , such authorities, she said, were inexorably " minder-minded " The society was working hard to get mor nurseries set up, and much was to be hoped from th conference on war-time nurseries to be held under th chairmanship of Lord Horder on Oct 29

CANTEENS AND HYGIENE

The need for good canteens was also discussed freely Again much turns on the confidence existing between th management and the workers Some employers provid no canteens, some hand the canteen catering over to contractor who makes little attempt to provide good food or serve it tolerably In other firms the workers take a share in running the canteen and can see to it that the food and service are good Mrs **Towers** told how she had worked in a West Country factory where a canteen was ultimately provided after much pressure , but the food was uneatable and she finally found herself doing 12 hours a night, seven nights a week, and travelling an hour each way, on a diet consisting largely of tea and cigarettes Faulty diet of this kind cannot fail to cause ill health and absentee-ism Poor hygiene in the factories must add to the danger , little was said about this during the discussion, but investigations by the organising committee show that ventilation and heating are grossly defective in some factories and that toilet facilities may fall below the level of the most elementary hygiene and decency Thus in one factory three basins are filled with hot water in which 60 girls have to wash their hands , in another there were recently 200 cases of impetigo, and a department employing about 200 had five washbasins and four towels , in another girls have to ask for a pass to go to the toilet and there is no ventilation in the lavatories, which are permanently blacked out

---

The session passed unanimously the bill to regulate supplies and distribution of food by registration and rationing, control of prices, school feeding, and by the provision of canteens and communal kitchens

In England Now

A Running Commentary by Peripatetic Correspondents

The student of human nature who wants a new field for observation should try the wardroom of one of H M ships in war-time Excluded for months on end from all normal associations—from the good earth (whoever has experienced the nostalgia for a patch of land in which to dig, bred by months of unrelieved seascapes, can understand the popularity of gardening among sea-going men), from trees, animals, weather that could be remotely related to a modest idea of summer, and above all from the companionship of the opposite sex—members of the mess settle down each to an individual level, some giving more in one way others in another, and a few taking more than they give I fancy they all go through a cycle, almost as regular as the menstrual one, of depression followed by elation, each phase of depression always lasting for the same number of days There are some people whom nothing seems to shake, and who are nearly always ready with a smile and a joke , and yet occasionally when off their guard they too seem a little less ready with their banter than usual Once in a blue moon there comes the big day when it is possible to entertain for an hour or two some of the ladies of E N S A who so heroically come to the most outlandish places to cheer the troops The change in atmosphere on the morning of the party fully justifies Freud in assuming sex to be the root of all behaviour The mess is split into three parties There are the less junior members who have a wife and family tucked away somewhere and who are not really in the running " But if we were, by Jove " You have to watch this lot pretty carefully or they will have sneaked her away into a corner before you have had time to get your cigarette-case out Then there are the quiet, introverted kind who will probably take a bad fall if they have not done so already, and who will probably marry late They enjoy the party and hand the drinks round beautifully, but do not get a chance to develop an attack in the short time and limited field available in the wardroom The third type is the thorough extrovert who makes, in a specified time, more noise and greater impression on the target than anyone else , they remind one of a barrage from the close-range weapons They usually sweep the girls off their feet at the first encounter and beat off all opposition for the duration of the party

Alas the ladies have come and gone Tomorrow we shall be back to our old selves again and the difference will be as that between leavened and unleavened bread I think I know to which of the last two groups I belong but it must be time for a change All I got was a glimpse of a blonde head and a well-turned ankle and a good view of the back of the Commander's neck

* * *

The course of propaganda never did run smooth , in an evacuee hostel it becomes a kind of switchback, even though you have the ear of your public and were once a doc yourself At our hostel two cases of diphtheria broke out at the end of June within a day or so of each other One of the patients was a twin, and both of them were called Angela so that a general air of confusion must be expected in this account which can only be distinguished from "The Comedy of Errors" by differences in style Well then · the twin, Angela A aged 5 had been immunised with her sister four or five months before awkwardly enough and she had had no known contact with a case of diphtheria But Angela B aged 6 had only been back for a few days after four weeks in hospital with scarlet-fever We had already had a stormy time with scarlet fever, so we were glad enough to submit to a full-dress investigation Throats were swabbed and offers of immunisation were scattered broadcast Angela A., however had shaken the confidence of our mothers Had she not been immunised and had she not "got it ' after all ? She had They shook their heads at our glib arguments pinning their judgment to facts as inopportunely represented by the case of Angela A Only 8 mothers out of the 30 thought our guess was better than theirs and allowed their children to be immunised The swabs all came back negative, and there were no more cases until the two Angelas returned from hospital, 6 weeks later Ten days after the return Angela A. s twin sister Brenda A developed symptoms and was sent to hospital Here was a smack in the eye for propaganda The medical officer of health came and took swabs of Angela A s throat, and the Klebs-Lœffler *bacillus* was grown from her postnasal discharge Back she went to hospital Rather sheepishly we brought up the topic of immunisation again The mothers didn't think a lot of it they were too polite to say so, but they sniffed rather eloquently But help was on the way Angela A. had sunk us, but her twin Brenda with a nice sense of fair play, threw us a lifebelt She came home in a fortnight, never having had a positive swab This was a test case, and one which nobody could sniff at Twins I mean, everyone knows how ready twins are to catch the same thing , and then Angela and Brenda A. had been inseparable after Angela came back from her attack in hospital If Brenda hadn t got it, it must have been because of that immunisation It was as clear as mud I began a telling campaign based on these arguments, and went on to talk of winter—blackout—close quarters —closed rooms Gradually they came round, and now, at the beginning of October all the children are in the thick of being immunised and we have had no more infectious cases That s a bit of luck

* * *

What are the motives behind the thousands now being bled to help stock the blood-banks and the tens of thousands who await the call ? And what do they imagine happens to them when they are bled ? Some enrol to experience something new, others because they think or their doctors have told them, that they suffer from blood pressure whereas a very few are actuated by the desire to secure the interest and possible admiration of their circle , the vast majority, however are moved by loyalty to their country s cause and a genuine desire to give their blood because it is needed Most of the volunteers are phlegmatic and their desire to serve costs them little in anxiety or discomfort But an important minority must resolve conflicts and overcome fears and doubts before reporting for duty, and these deserve the full sympathy of the phlebotomist In peace-time they are represented by those relatives who loathe nothing more than the thought of giving blood and who would never volunteer were it not for a loved one in need Some of the volunteers, who have had no opportunity of discussing the matter with one who has been "blooded,' imagine that an artery will be opened in the arm and that the blood will be caught in some sort of vessel (presumably on the down-throw) , later stitches will be put in (if the bleeding *can* be stopped) and the exsanguinated victim will be sent home in the hopes that new blood will be made during the week-end It says a lot for the altruism of these apprehensive realists that they have steeled themselves for the ordeal In small towns, the dangers of giving blood are often magnified by stories circulating of oozing which the doctor could not stop of bleeding which recommenced that night in the pictures of faints at the tea-table of lumps in the arm of "the septics ' and of all manner of conceivable ailments attributed to blood-letting On the other hand some expect an operation as trivial as the grouping test—"I find my bus doesn t go for another twelve minutes so I thought you might take my blood now

The introspective volunteer will arrive at the centre with a dread of experiencing pain (often they compare their feelings to those experienced in the dentist s waiting-room), a fear of seeing blood especially his own, and of making a fool of himself in the presence of others In case our donor-elect happens to be of this stamp one cannot expend too much thought and care on him when he is called on for the first time It is a natural and deeply rooted instinct to feel faint at the sight of one s own blood and even the thought of it will cause some people to feel squeamish It is, therefore an injustice to resent the attendance at the bleeding centre of those who are *not* very stable in their vasomoter systems, and to regard them contemptuously as "neurotic" The fainting is a "protective ' reflex for the consequent fall of blood-pressure helps both to lay the subject flat and also to arrest the hæmorrhage It is as well to satisfy oneself that the volunteer is in good health and willing the fact that the candidate was well on enrolment two years ago is *no* guarantee that he or she is fit to be bled now. We find it adds enormously to the comfort of the donor if he receives a small intracutaneous injection of procaine prior to the insertion of the ' donor needle The two who in error received an injection of sal volatile were presumably of the phlegmatic type or they would have complained or can this diffusible stimulant have anæsthetic properties yet to be explored ? It was only when we set about reviving a colleague's wife with a tot of procaine that we realised that the dispenser had put up both these substances into similar bottles

How grateful we are to those who perfected the present M R C needles and the bottle with its fashionable waistline ! A wider neck perhaps would have been preferable, being *more* readily adaptable for bottling gooseberries during the close season for blood, but otherwise we have no complaints It is unnecessary, and uncomfortable for the donor to employ too great a pressure on the sphygmomanometer cuff. While the needle is being introduced through the anæsthetised spot an initial rise to about 50 mm Hg is desirable and the donor should be *told to squeeze* a bandage or a one ounce screw-capped bottle in his fist. As the blood begins to flow the pressure can be lowered *to 30 or* 20 mm and it is surprising how often no pressure at all is needed even if the donor has partially relaxed his hold on the bandage or bottle Some of our volunteers turn the scales at fifteen stone while others are barely seven It is unfair to bleed *them to an* equal *extent* The maximum donation should be 420 c cm and some subjects are best cut down to 300 c cm or *even* less In these days everybody is an allotment holder and a fire-watcher, in addition to doing more than an ordinary day s work The *bone-marrow tax* therefore should not exceed 5–7% and it should be collected at the most convenient time for the taxpayer—*after business hours*, or on Saturday afternoons and Sundays

* * *

"Doctor, here's your hat ! " A book of medical reminiscences was published by an American doctor a few years ago with this engaging title I did not read the book for I knew that, for me, the title was all How many times has my decrepit tile been handed to me with these words A lady arrived at the nursing-home for her confinement with my hat among her luggage, and refused to return *it to* me until her baby was born Black hats in her system of hagiology were lucky ; even my promise to find her a black cat in exchange was of no use It had to be a hat, it had to be a black hat and it had to be mine If this was my hat's strangest experience it has had another more humiliating One of the difficulties that a doctor has about a hat is its safe lodgment in his patient's house Too few halls are today decorated with a hat-stand or even a hat-rail The hat, however, must be left in a position that is at once obvious and unobtrusive, the staircase lintel, if such there be, is the position of choice "I will look in to see David again on Tuesday, Mrs Jones," with one's hand travelling lightly down the banister, "I'm sure that by then we shall find him (ah, yes, this is mine," as one's hand comes directly against a familiar object) "very much better" Nothing could be more simple and one is on the doorstep, hat in hand The lintel absent or inadequate, it is necessary to look around for another lodging It was thus that I was one day searching a hall when I saw a coffin-like glass case in which fish of varied colours were swimming I trustfully put my hat on the top of this miniature aquarium I was mistaken, for its sixth and upper side was open to the air My hat was rescued by the proprietor just before it completely submerged, and was returned to me with a goldfish inside This problem will in any case be solved by the too swift passage of the summer, for the doctor who can put on his overcoat and leave his hat behind him must suffer from amnesia to an unusual degree Three further clinical points about this interesting disorder It must be of recent origin, since any late Victorian or early Edwardian physician who walked down the garden-path without his silk hat on his head must have suffered irreparable loss of prestige Secondly, the malady is not entirely specific since it may embrace other objects, such as stethoscopes and ophthalmoscopes Thirdly, in advanced cases the symptom may be displayed in unusual circumstances A few days ago the gardener brought in a forage-cap which he had found lying at the foot of some raspberry-canes He had his theories about this cap One was that the cook, his friend, had been receiving the licentious soldiery in the summer-house, the other that the thieving, scrounging so-and-so's had been after his peas My wife restored calm when she recalled that a few nights before I had put on my Home Guard uniform for the first time and had mowed the lawn in full kit to accustom myself to these unusual garments The night was warm, the grass was long, the mower was stiff and I was sweating uncomfortably round the forehead I discarded my convict cap Thus a few days later it was held in front of me, a poor shrunken thing "Major, here's your cap!"

* * *

The autumn health publicity campaign of the Ministry of Health has begun, and great things are promised us H M Bateman in his posters and Arthur Askey in his comedy film can be relied on to do their stuff, and there are to be window displays and talks by the B B C But on the literary side, it seems, there is to be no high art, just three very plain statements hardly worth the name of slogans—"Coughs and sneezes spread diseases Trap the germs by using your handkerchief Help to keep the nation fighting fit" Not very lively, are they? And unless we use paper ones, which are scarce these days, it seems to me that our handkerchiefs will merely trap the germs temporarily and release them later on the unsuspecting housewife or maid at the wash tub So as an unofficial Poet Laureate, spurred to action by grave current events, I submit the following metrical version which may point the way to saving a deserving life without mentioning any particular brand of disinfectant

Coughs and sneezes spread diseases
Trap the germ before it seizes,
Do not think our slogan cranky,
Wrap the devil in your hanky
So you'll keep the nation fit,
Able then to do its bit,
Healthy, well and superhuman—
All except the washerwoman

* * *

It surprises me that no peripatetic correspondent has commented on the unique position which the cigarette holds in these troublous times Though it cannot be counted as foodstuff or munition of war it has gained for itself a special controller, a special commission to buy supplies from abroad, and a special place in th lend Act I have read or heard the number of of cigarettes that are smoked every day and t sands of tons of tobacco that are imported eve but having no memory for figures I have made calculations If, I said, one in twenty of the smokes cigarettes (surely a modest estimate) average consumption per smoker per day is 5 (again a modest estimate), then some 10 cigarettes are smoked every day which at 1s 6d means £37,500 going up in smoke daily Now, little doubt that the cigarette has become an part of our social system It serves as introdu strangers on a train journey, it breaks the icy a ness among distant acquaintances assembled for a it is the hall-mark of the gentleman when the over If you cannot produce a well-stacked silver cigarette-case, or worse still, if you refuse t one from such a case, you are suspect for the rest evening The cigarette relieves the monotony tedious day (many a man never smoked till he army), it soothes the distracted mind, it alla pangs of hunger, it may even, according scientists, disinfect the air we breathe And w its virtues have been extolled, we have to smoking is but a bad habit—a habit which can us broken without detriment to the habitue, a habit many folks never acquire and are none the worse lack of it For some it is a form of worship church-going, they cannot do without, but for us it is a self-indulgence which with a little eff could well give up We might even class the smo the road-hog who uses petrol for pleasure, but that be hitting at the liberties of the British wor man? Some smokers defend themselves by to the revenue which tobacco brings in, but in these when every inch of shipping space is needed for dities to beat Hitler that is a poor excuse May I that I confess to a sneaking envy and admiration pipe-smoker? The only thing about him that is the time he wastes in filling his pipe Now w quite another kettle of fish, it is home-produced, is tenths tax, and only the very rich can consume too of it, so that to drink the stuff is a real act of patrioti Being a Scotsman who has lately forsworn the weed, like to be overflowing with virtue and good spirits

On the related subject of food, I'd put the " g w vegetables" campaign among our few triumph —of this war I don't know how much extra food it produced, but it has sent many of us townsfolk ba the land to discover or re-discover the virtue of up mother earth It has been a hobby and a healer as well as providing the physical exercise that indoor worker needs, it has also been a great lev giving employer and employee a common bond of inter It has even supplanted "shop-talk" when mem our fraternity forgather I wonder if they cultivate allotment and vegetable patch in Germany

BRITISH HOSPITALS ASSOCIATION

Sir Bernard Docker had a cheering statement to the annual meeting of the association on Oct 24 For first time the association is distributing money As agent of the Government it is remitting the 50% grant of additional salaries being paid to the nursing staffs of the pitals (*Lancet*, Sept 6, p 292) The council have adopt statement of policy explaining the relationship between association and the Nuffield Provincial Hospitals Trust, is largely an attempt to define terms Wherever pract the term "coordination of hospital services" will be u instead of "regionalisation" The association is calling erstwhile regions "areas" and will try to make their ries conterminous with those of the Nuffield "divisic Areal committees will deal with the special problems of voluntary hospitals apart from those they have in with the council hospitals Sir Bernard regretted that lation had not put upon voluntary hospitals a share of responsibility for providing hospital accommodation Bernard also spoke of the anxiety felt by many hospit about the shortage of staff owing to the refusal of the Minis of Labour to regard hospital work as war work His rema were strongly endorsed in the discussion which followed it was even suggested that some hospitals might have to c because the necessary lay staff was no longer available

Parliament

FROM THE FLOOR OF THE HOUSE

MEDICUS M P

IT was in the first year of this world war that I left e House, in June, 1940 to be precise, and it is in the ird year of the war, in October, 1941, that I return to is column Not that Service commitments kept me vay from the House entirely—it is laid down in gulations that an M P shall get leave to attend to his rliamentary duties—but such visits as I could make ere different The House to which I return is different o A Service colleague saying good-bye to me said, Well, keep 'em up to it We support the Government it no-one is infallible" The House I left in 1940 had ist rallied to the new Government to meet a mighty iock—the House to which I return in 1941 is remaking ie forms and procedure of the House to meet the rcumstances of a war in which Parliament is a chief of ie forces fronting the enemy There is active and onstructive criticism There is provision being made r the first time in modern parliamentary history, for ie taking of votes and recording the division of opinion hen the House is in secret session There is criticism f the somewhat clumsy expedient of an official non-overnment spokesman speaking from the "Opposition" ench (which supports the Government) so as to carry ut the "opposition" duties without which the parliamentary machine does not function There is an icisive bite in many questions put to ministers in which real opposition, in matters of detail, expresses itself But out of details in Parliament spring principles on hich Governments may be attacked

* * *

There have lately been several occasions in Parliament n which the voice of criticism has reached full opposiion strength—but not an opposition on party lines A lebate *on proposed changes* in Service pay and dependints' allowances introduced by Sir Walter Womersley, Minister *of Pensions,* and *supported* by Mr Wilfred Paling, the parliamentary secretary, was received with a inanimous *chorus of fierce criticism* from Labour, Liberal and Conservative alike The House wanted a straightforward *increase of dependants' allowances* The Minister offered an increase of grants to be made hrough the machinery of the Unemployment Assistance Board This lining up of Army and other Service dependants outside the offices of the U A B appealed neither to Viscount Hinchinbrooke in the uniform of a Midland regiment, nor to Miss Ward a member of the War Grants Committee with an expert knowledge of all the details of the grants, nor to Mr Dobbie, another member of this committee

The Minister tried to bluff it out and his parliamentary secretary backed him up but, most astonishingly, Sir Walter Womersley said in a broadcast the same evening, that the proposals were received by Parliament with "general approval" Chase my parliamentary secretary round the Speaker's chair—as Mr Nat Gubbins M P, might say! Briefly this scheme for dependants was rejected by the mass opinion of the House on the ground that it was administratively unworkable and that it was unjust The Minister still smiles about it in public—but behind the scenes desperate efforts are being made to evolve something more acceptable—and the House is not likely to be complaisant And ministers can be changed if necessary

* * *

Another occasion was a debate on the refusal by Mr Morrison as home secretary to allow Mr McGovern to visit North and South Ireland Mr McGovern is a member of the Maxton party of three who are against the war but who state that they are anxious to do nothing to impede the war effort One of Mr Morrison's reasons for the refusal was that he did not consider that Mr McGovern's visit to Ireland "would be helpful" to the national effort But is it Mr Morrison's business to decide that? It was argued, by the Conservative M P who brought the matter up before the House that this was not Mr Morrison's business—that it was essential to the M P to be as free and unfettered as possible in carrying out his duty as an M P The criticism of the Home Secretary by all parties in the House was so hostile that the Prime Minister had to come to Mr Morrison's rescue And there was an uneasy questioning about whether there was "any danger of a division" not in the House, *but in the lobbies outside*

No matters of this kind touch on the House s support *for the Prime Minister* he stands head and shoulders above all his ministers in the cabinet and out—indeed it is a *pity some of them are not taller* As criticism develops—as a result of the revelations of the Gort dispatches, as a result of criticism with regard to British aid to Russia, and as a result of other matters which crop up—individual ministers' reputations may be damaged and they may even be dropped But the Prime Minister strengthens his hold on the House

* * *

One disadvantage of the McGovern debate was that it cut down a debate on the health of the nation to a half-day Mr Ernest Brown had recently made a statement on the inquiry to be held on the relations of voluntary and publicly controlled hospitals in the future A useful piece of work, but not of priority importance at the moment Medical man-power, the rise of tuberculosis and its relation to the conditions of war-production and existing epidemics of typhus in Europe are all of greater urgency The interim report of the Shakespeare committee on medical man-power, which has been written but not published is known to be a purely interim proposal for the setting up of regional committees The setting up of a method of close coördination of all branches of medical work in the war will need to be pursued by other and more vigorous means if this is to be effective One of the speakers in the debate was Prof A V Hill, who spoke in favour of a state medical service without defining the machinery of the service The B M A Medical Planning Commission PEP medical and health committees of other organisations and much discussion in committees in and around Parliament are all considering the problem of the health and medical service of the nation And in the new parliamentary session—the present session is ending shortly—a larger scale debate on health and medical questions is to take place

It is hoped that this debate will give opportunity for consideration of the health aspect of food rationing, of the increase of health services in war factories and generally of how, to keep the nation—as one member said in the last debate—fighting fit for the work of production

Our Nutrition Policy

In the pleasantly informal atmosphere of the luncheon hour on Oct 21, Lord LISTOWEL in the House of Lords gave the *Government an opportunity to describe* how they were safeguarding the children's food in war-time The problem was not *controversial* but it was urgent The Government's milk scheme and school meals were our new antidotes to poverty and malnutrition and Lord Listowel hoped they would become no less permanent a feature of our social services than free education Indeed teachers have discovered that a school meal is a practical demonstration of character training and dietetics, and is as valuable as regular classes or organised games

Lord WOOLTON said that war had altered the whole nature of the nutrition problem As a result of the equalising effect of the ration book the nation was living on a diet which was based on the average needs of the family But it was not designed to meet the needs of special classes of the community and there was some danger that those who required special consideration either for the growth of their bodies or for the maintenance of more than average physical strength, might find the ration-book diet insufficient At present there were 5 million children in the elementary and secondary schools and only 300,000 were receiving meals in school The provision of school meals was uneven in a few areas as much as 30% of the children were having meals in school, in others there was little or no provision Not all local authorities had realised the implications of the war-time diet scale, and there was no doubt that many had met with difficulties regarding equipment premises and finance Yet in some areas up to 50% of the parents would like their children to have dinners in school and are willing to pay for them

The Chancellor of the Exchequer had now agreed that from Oct 1 the grant in respect of the provision of meals for children attending public elementary schools was to be increased by a further 10%, with an overriding maximum of 95% of the loss incurred The minimum rate of grant would now be 70% and the average rate approximately 80% Priority supplies would be provided to enable school canteens to serve balanced meals of the type which medical and scientific advisers considered necessary for the growth and health of schoolchildren These provisions would apply to all schools The cooking depots for use in emergency, which had been set up by local authorities and were now lying idle, were to be brought into action now and kept bright and polished in the daily service of the children of the nation They were capable of providing 300,000 meals a day, and the number would be increased to 400,000 British Restaurants and emergency meal-centres would also play their part, and their equipment, subject to suitable safeguards, would be used and where it was necessary to start new kitchens equipment would be available from the Ministry's pool The President of the Board of Education was seeking to raise the proportion of children receiving milk under the milk in schools scheme from the present 60% to as near 100% as possible To this end the whole cost of providing free milk to necessitous children and handling the milk in the schools would be reimbursed by the Exchequer

So much for children But, Lord Woolton pointed out, we have not only to preserve life but to defend liberty The principle adopted to secure the health of children—to see that they should be fed where they were congregated—had also been adopted for industrial workers Canteens would be divided into three groups, according as they catered for the heavy worker, the medium-heavy worker and the sedentary worker, and the Government would provide the appropriate food accordingly Before the end of this year 85% of the mining population would have a supplementary ration served at the pit-head

Lord HORDER, in welcoming the Minister's statement, said that so far no overt signs of malnutrition were to be seen among our people, but if we delayed until malnutrition appeared we might have waited too long, for malnutrition left a permanent scar Evacuation had undoubtedly acted as a deterrent against deficiency diseases in children, because sun and air were essential in preserving nutrition But we did not know how far our children might be from malnutrition , for science could not measure the margin of safety Children were at the mercy of chance in any rationing scheme, for with most mothers knowledge marched a good way behind affection, and school was the only place where defects might be made good and hazards warded off He felt that this was a red-letter day in the annals of children's nutrition Everybody must help and they must aim at as many meals as possible in as short a time as possible

The Battle of the Books

The Minister of Information lately said that ink has done much to sustain and improve the modern social system It is the staple of freedom, knowledge and entertainment But ink can do nothing without its colleague paper, and Lord SAMUEL received warm support in the House of Lords on Oct 23 when he pleaded for some indulgence for the publishers of books. Noble Lords seemed to feel that paper-saving might well begin in Whitehall Entertainment and education are part of our war effort and the public are seeking both today from books in a greater measure than ever before Libraries and universities are unable to obtain school books and technical books which they have ordered, and Lord HORDER sent a message to say there is an urgent need for the release of paper for printing books for the doctor, the medical student, the nurse and the civil defence worker He gave as an example from his own knowledge an excellent book on first-aid which is out of print and cannot be reprinted for lack of paper, and added that the "chaotic state" of the printing and binding trades are causing from 4–6 months' delay in the publication of what books there is paper for Knowledge of science could not be maintained unless there are books to feed it Lord SAMUEL pointed out that the paper used for books is obtained from home sources and is only 1 5% of what the country uses for other purposes We must concentrate on the war, but what are we fighting for, Lord Samuel asked We are fighting for the intellectual and spiritual things which we value and it would be a tragedy if they were to be trodden under in the fight The Archbishop of CANTERBURY held that we cannot be effectively at war unless we are sometimes prepared to get outside it and above it, and for many books were the easiest means Restriction of paper unfortunately by no means meant that only the best books were published Lord ESHER thought that the publishers had perhaps not done all they might to solve their labour problems Lord ELTON said that the books we exported project Britain abroad, and declared the least pretentious book was a better form of escapism than alcohol or astrology He warned his listeners that a too severe restriction of paper might easily slide into a kind of censorship Lord SNELL replied for the Government regretfully, but said the book trade had received more favourable treatment than newspapers or periodicals He admitted his own indebtedness to books and looked forward to the day when they would once more provide unrationed nurture for our times Lord SAMUEL thanked him for the spirit rather than the substance of his reply and acclaimed him as a literary Doctor Jekyll and an official Mr Hyde

QUESTION TIME

School Meals in Scotland

Replying to a question Mr T JOHNSTON said I hope to secure an immediate and substantial development of school meals service by arranging for advantage to be taken of facilities provided by the Minister of Food, and where these are not available by encouraging education authorities to make their own provision The financial aid available to education authorities is being increased Parents who are able to pay will be expected to pay Scots Law presently permits food to be provided for necessitous children only when the child is unable by reason of lack of food to take full advantage of the education provided But malnutrition should be prevented, and a short bill, designed to give education authorities power to supply food free of charge to necessitous cases without waiting for evidence of malnutrition, will be introduced in the near future

Tuberculosis in Scotland

Mrs A HARDIE asked the Secretary of State for Scotland in what districts in Scotland the increase in notified cases of tuberculosis had taken place —Mr JOHNSTON replying gave the following figures —

1938			1939			1940			1941 (first 41 weeks)		
Pul	Non pul	Total	Pul	Non pul	Total	Pul	Non pul	Total	Pul	Non pul	Total
4793	2772	7565	1657	2140	7097	5200	2504	7704	4548	1988	6536

Pul = pulmonary

Infant Mortality in Scotland

The latest infant-mortality figures available for Scotland are those for the first six months of this year Comparing these rates with the average of the rates for the first six months of the three years 1937, 1938 and 1939, the burghs showing the largest percentage increases are Dumbarton, Rutherglen, Hamilton and Paisley Considerable increases are found in the counties of Nairn and Sutherland, but the small number of births in the first six months of 1941 renders any comparison unreliable (Mr JOHNSTON replying to Mrs HARDIE)

War-time Nurseries in Scotland

Ten local authorities in Scotland have submitted definite proposals for the establishment of war time nurseries, and these proposals, which provide for 39 nurseries, have all approved Of the 39, there are 2, each accommodating 40 children, in full operation, and 14 which were already in pa operation at the date of the circular are being brought into fuller operation (Mr JOHNSTON replying to Mr McNEIL)

Deaths after Vaccination

In reply to a question the MINISTER OF HEALTH stated the deaths of children under five assigned to vaccinat numbered 5 in 1938, 1 in *1939 and* 6 in 1940 , but I *am* advised that this classification does not rule out the probability that such deaths may have had other contributory causes

Registrar-General's Reports

Sir Ernest Graham Little asked the Minister whether he ould secure the resumption of publication of the Registrar-eneral's Reports, cessation of which constituted a serious ndicap on medical research, and was successfully avoided the last war —Miss F Horsbrugh replied The prepara- on of these reports has not been discontinued, though it is gretted that war time conditions have delayed the comple on of the report for 1939 It has been decided, however, to int in the first instance a very limited edition of this volume hich will be held by the Registrar General and made avail- le for consultation and study by Government departments d other bodies or persons having an acknowledged interest its contents The interests of medical research will receive mpathetic treatment under this arrangement

Doctors for Pensions Appeal Tribunals

Mr W W Wakefield asked the Minister of Pensions if, view of his recent undertaking that he would consult the inister of Health as to the supply of doctors for pensions ppeal tribunals, he could now state what was the present osition.—Sir W Womersley replied I have stated that I hall keep the matter of pensions appeal tribunals constantly mind in the light of the findings from time to time of the hakespeare Committee I am asking that committee to give e their views on the availability of suitable doctors for ppeal work

Hospital in Antigua

Dr H. B Morgan asked the Under Secretary of State for he Colonies whether the Colony Hospital in Antigua, British Vest Indies, was still in the state it was in February, 1939, adly in need of repair, with rotten floors, leaking roofs, roken doors and poor sanitation, whether temporary epairs had yet been done, and when it was proposed to ebuild the hospital properly so that good medical work for he island inhabitants might be done —Mr G Hall replied Owing to the financial position of the colony it has only been ossible in recent years to effect the minimum running repairs o the Holberton Hospital in Antigua The question of ebuilding the hospital, which is agreed to be necessary, has een considered by *the comptroller for development* and welfare in consultation with the governor Plans will be rawn up by a qualified hospital architect now in the West ndies This architect will shortly be undertaking a survey f hospital buildings in *the Eastern Caribbean colonies* and British Guiana, financed by a grant under the Colonial Development and Welfare Act

Medical Board Rejects

Sir Robert Young asked the Minister of Health whether he was aware that many men were turned down for the various forces by the medical boards on account of physical disability, and placed in class III *or* IV, *and whether he* would consult with the War Office, in the interests of the future health of the nation, so that each man should be informed of his particular physical disability, when if it was anything requiring attention he could consult his own medical doctor or officer —Mr E Brown replied I will communicate with the Minister on the matter

---

Bee Stings —Mr S B Ralston of Bearsden, Dumbartonshire, writes I have worked with bees for some 20 years, using a veil but with bare hands, and therefore have a large experience of stings A moderate number of stings have little effect, except a slight local redness and later itchiness, with no swelling, but 20–30 stings have had a more severe effect, and recently even fewer than 20 The effects are, successively (1) a feeling of heat and stuffiness inside the veil, (2) increasingly heavy pounding of the heart, (3) rush of blood to the head, with bloodshot eyes, (4) a sick feeling but no vomiting, (5) giddiness tending towards momentary unconsciousness (6) gradual recovery with profuse perspiration, (7) nearly full recovery in about two hours The attack itself seems to take a long time, but actually is only a matter of minutes The procedure I adopt is to lie flat on my back with my head slightly raised, I do this at once in the garden, but well away from the hive Then when the giddiness is over I go indoors and take a warm bath and get a very necessary change of clothing Finally I sleep for an hour or two

Letters to the Editor

MALNUTRITION IN THE COLONIES

Sir,—You have drawn attention to the subject of planned nutrition for our Crown Colonies in your leader of Oct 4, and I hope you will go on turning a kindly eye on this subject for the benefit of the less well informed at home Little was really done before the war, though the Moyne Commission brought out the appalling state of nutrition in the West Indies, one of our oldest colonies In Africa, medical development has largely been due to the keenness of individuals rather than to a defined nutritional policy This is borne out by the dearth of nutritional appointments and of postgraduate training facilities, and by the lack of standing committees directed to the study of nutrition Nor have educated Africans taken much share in a problem which is primarily their own A more active policy was being foreshadowed at home before the war in the Colonial Advisory Report no 1 Report no 2, which was that of the colonies themselves, showed how little active concern for nutrition they had displayed up to that time The work of the Medical Research Council, Dr Platt's visit, and the proposal to establish research scholarships before the war all show awakening interest Credit for what has been done so far, however, must go largely to men like Stannus, Lowenthal, Pillat and Wilson, who spent the greater part of their lives in Africa and contributed much of what is known about tropical malnutrition They knew their environment and the people they lived among—essential preliminary knowledge for most research in Africa, since Africans are shy of inquirers until they know and trust them The Alfred Jones Laboratory was an excellent example of the value of continuity, but is now closed down If nutrition is to be tackled seriously in our tropical possessions this can best be done by men who live there Its study needs a director and whole-time staff and the same backing as that given to the sleeping-sickness campaign in recent years Most of the medical advisers at home and the directors of medical services in the colonies have had a greater interest in medicine and hygiene than nutrition, there have been few Sir Thomas Stantons We need permanent nutritional departments at home and in the colonies, staffed by men who are not only qualified for the work but are vocationally interested in it

Moreover, colonial nutrition is judged from too narrow an angle What collateral partnership is there between the study of nutrition and research in agriculture and fisheries, veterinary science, animal and plant nutrition? It is the job of agriculturists to improve the cereal crops which are so badly needed in Africa, to check the growing of uneconomic crops, to prevent soil erosion, and to fight pleuropneumonia and rinderpest in cattle To the Africans agriculture has always appeared as a child of the political administration and its potentialities have never been recognised There has been little constructive attempt to create interest in nutrition, few know, for example, that Kew Gardens introduced new foods and the first orchard crops to Africa In many cases those orchards have been left desolate, or have become local botanical gardens, merely decorative and no longer serving the purpose for which they were intended Lack of continuity is responsible, Kew is forgotten and unhonoured by the present generation in Africa

Essential partners in African malnutrition are the venereal diseases Gonorrhœa is endemic and widespread and is responsible for the bulk of physical unfitness among recruits for much lost labour and for shortened expectation of life It is as much a disease of poverty and ignorance as leprosy, but instead of being of Biblical antiquity it has come with the changing world we have created for Africa—with our trade development and with the breakdown of old laws which have been replaced only in part by new ones Even today we can do relatively little for lepers, but for gonorrhœa we now have specifics and could do much

Perhaps after the war we shall hear more about the colonial research fund, and perhaps more research facilities will be given to Africans and those whose interest is in the country Since war broke out we have for children attending public elementary schools was to be increased by a further 10%, with an overriding maximum of 95% of the loss incurred The minimum rate of grant would now be 70% and the average rate approximately 80% Priority supplies would be provided to enable school canteens to serve balanced meals of the type which medical and scientific advisers considered necessary for the growth and health of schoolchildren These provisions would apply to all schools The cooking depots for use in emergency, which had been set up by local authorities and were now lying idle, were to be brought into action now, and kept bright and polished in the daily service of the children of the nation They were capable of providing 300,000 meals a day, and the number would be increased to 400,000 British Restaurants and emergency meal-centres would also play their part, and their equipment, subject to suitable safeguards, would be used, and where it was necessary to start new kitchens equipment would be available from the Ministry's pool The President of the Board of Education was seeking to raise the proportion of children receiving milk under the milk in schools scheme from the present 60% to as near 100% as possible To this end the whole cost of providing free milk to necessitous children and handling the milk in the schools would be reimbursed by the Exchequer

So much for children But, Lord Woolton pointed out, we have not only to preserve life but to defend liberty The principle adopted to secure the health of children—to see that they should be fed where they were congregated—had also been adopted for industrial workers Canteens would be divided into three groups, according as they catered for the heavy worker, the medium-heavy worker and the sedentary worker, and the Government would provide the appropriate food accordingly Before the end of this year 85% of the mining population would have a supplementary ration served at the pit-head

Lord HORDER, in welcoming the Minister's statement, said that so far no overt signs of malnutrition were to be seen *among our people, but if we delayed until malnutrition appeared we might have waited too long*, for malnutrition left a permanent scar Evacuation had undoubtedly acted as a deterrent against deficiency diseases in children, because sun and air were essential in preserving nutrition But we did not know how far *our children might be from malnutrition , for science could not measure the margin of safety* Children were at the mercy of chance in any rationing scheme, for with most mothers knowledge marched a good way behind affection, and school was the only place where defects might be made good and hazards warded off He felt that this was a red-letter day in the annals of children's nutrition Everybody must help and they must aim at as many meals as possible in as short a time as possible

The Battle of the Books

The Minister of Information lately said that ink has done much to sustain and improve the modern social system It is the staple of freedom, knowledge and entertainment But ink can do nothing without its colleague paper, and Lord SAMUEL received warm support in the House of Lords on Oct 23 when he pleaded for some indulgence for the publishers of books Noble Lords seemed to feel that paper-saving might well begin in Whitehall Entertainment and education are part of our war effort and the public are seeking both today from books in a greater measure than ever before Libraries and universities are unable to obtain school books and technical books which they have ordered, and Lord HORDER sent a message to say there is an urgent need for the release of paper for printing books for the doctor, the medical student, the nurse and the civil defence worker He gave as an example from his own knowledge an excellent book on first-aid which is out of print and cannot be reprinted for lack of paper, and added that the "chaotic state" of the printing and binding trades are causing from 4–6 months' delay in the publication of what books there is paper for Knowledge of science could not be maintained unless there are books to feed it Lord SAMUEL pointed out that the paper used for books is obtained from home sources and is only 1 5% of what the country uses for other purposes We must concentrate on the war, but what are we fighting for, Lord Samuel asked We are fighting for th intellectual and spiritual things which we value and would be a *tragedy if they were to be trodden under* the fight The Archbishop of CANTERBURY held that w cannot be effectively at war unless we are sometim prepared to get outside it and above it, and for man books were the easiest means Restriction of pape unfortunately by no means meant that only the bes books were published Lord ESHER thought that th publishers had perhaps not done all they might to solv their labour problems Lord ELTON said that the bool we exported project Britain abroad, and declared th least pretentious book was a better form of escapis than alcohol or astrology He warned his listeners th a too severe restriction of paper might easily slide in a kind of censorship Lord SNELL replied for th Government regretfully, but said the book trade ha received more favourable treatment than newspapers periodicals He admitted his own indebtedness t books and looked forward to the day when they woul once more provide unrationed nurture for our time Lord SAMUEL thanked him for the spirit rather than th substance of his reply and acclaimed him as a litera Doctor Jekyll and an official Mr Hyde

QUESTION TIME

School Meals in Scotland

Replying to a question Mr T JOHNSTON said I hope secure an immediate and substantial development of scho meals service by arranging for advantage to be taken facilities provided by the Minister of Food, and where the are *not* available by *encouraging education authorities* make their own provision The financial aid available education authorities is being increased Parents who a able to pay will be expected to pay Scots Law present permits food to be provided for necessitous children on when the child is unable by reason of lack of food to take fu advantage of the education provided But malnutritio should be prevented, and a short bill, designed to give educ tion authorities power to supply food free of charge t necessitous cases without waiting for evidence of malnutritio will be introduced in the near future

Tuberculosis in Scotland

Mrs A HARDIE asked the Secretary of State for Scotlan in what districts in Scotland the increase in notified case of *tuberculosis had taken place* —Mr JOHNSTON replyin gave the following figures —

1938			1939			1940			1941 (first 41 weeks)		
Pul	Non pul	Total	Pul	Non pul	Total	Pul	Non pul	Total	Pul	Non pul	Tot
4793	2772	7565	4657	2440	7097	5200	2504	7704	4548	1988	65

Pul = pulmonary

Infant Mortality in Scotland

The latest infant mortality figures available for Scotlan are those for the first six months of this year Comparin these rates with the average of the rates for the first si months of the three years 1937, 1938 and 1939, the burgh showing the largest percentage increases are Dumbarto Rutherglen, Hamilton and Paisley Considerable increas are found in the counties of Nairn and Sutherland, but th small number of births in the first six months of 1941 rende any comparison unreliable (Mr JOHNSTON replying to Mr HARDIE)

War-time Nurseries in Scotland

Ten local authorities in Scotland have submitted defini proposals for the establishment of war time nurseries, an these proposals, which provide for 39 nurseries, have all bee approved Of the 39, there are 2, each accommodating 4 children, in full operation, and 14 which were already in parti operation at the date of the circular are being brought int *fuller operation* (Mr JOHNSTON replying to Mr MCNEIL)

Deaths after Vaccination

In reply to a question the MINISTER OF HEALTH stated the deaths of children under five assigned to vaccinatio numbered 5 in 1938, 1 in 1939 and 6 in 1940 , but I an advised that this classification does not rule out the probabilit that such deaths may have had ot few symptoms or because their symptoms are wrongly ascribed to other lesions present

The phrenico-costal sinus contusion was stressed because I feel it is proved that this lesion has an abdominal component to the force causing it, it therefore serves to direct attention to the fact that the abdomen is compressed with the chest—Dr O'Reilly was so much confronted with this aspect that two of his cases had the abdomen opened I fancy his fig 2, the radiogram of case 3, shows a phrenico-costal sinus contusion (these radiograms are of such general interest that it is a great pity they were reproduced as positives instead of negatives—they compare very unfavourably with those of Dr Deaner on the previous page)

The interpretation of the lung changes in any particular case may be so difficult that it is easy to understand them being described as just irregular This is especially true of cases dying some time after the injury when acute pulmonary œdema may complicate the picture Some degree of acute pulmonary œdema is the rule in these cases and the more hæmorrhagic forms of this may mimic the deep and often massive hilar contusions (these can be regarded as the contre-coup lung lesion) The action of morphia in preventing the onset of acute pulmonary œdema suggests that Dr O'Reilly was very wise to use it freely in his cases, the similar action of some anæsthetics indicates that perhaps the dangers of anæsthetics in blast cases has been exaggerated Since acute pulmonary œdema is benefited by venesection each case should be given careful thought before plasma-transfusion or the like is used

While I agree with Dr O'Reilly and Dr Gloyne that the importance of making a diagnosis of blast injury of the lungs is great I do not believe that it is any greater than making a similar pathological diagnosis in road and other peace-time accidents—cases which are almost regularly treated with complete disregard for the lung lesions

Derbyshire Royal Infirmary	G R OSBORN

CEREBRAL HÆMORRHAGE IN AN INFANT BORN BY CÆSAREAN SECTION

SIR,—The morbid findings in an infant, which Dr Lapage (*Lancet*, Aug 9, p 160) attributes to some constitutional factor such as deficiency of vitamin K, are of great interest on account of their strong resemblance to what is seen in patients with infective endocarditis who have been treated by a combination of heparin and sulphonamides This treatment which appears so attractive on theoretical grounds has been associated with fatal cerebral hæmorrhage in a proportion of cases and the brain at autopsy often shows diffuse extravasation involving particularly the white matter of the cerebrum so that large areas are converted into a hæmorrhagic jelly Elsewhere there are hæmorrhages on a smaller scale and having a distribution similar to that described by Dr Lapage The similarity of the pathological findings in the two states is a point in confirmation of the suggestion he puts forward regarding an alteration in the clotting power of the blood

London, S W 3	J H MULVANY

FOOD ADVICE FOR THE WAITING OUTPATIENT

SIR,—The part which doctors and nurses play in aiding the national food policy is at present small because nutrition is a matter on which they are seldom consulted by their patients except in cases of illness, and then it is more often the special diet than the general aspect that arises In spite of the efforts of the Ministry of Food that are everywhere apparent and applauded, enlightenment on the best food to buy within the restricted choice available and the most beneficial methods of cooking it are limited because the ministry lacks the means of reaching the housewife by personal contact A great opportunity to overcome this difficulty exists in the outpatient departments of hospitals and in the maternity and child welfare clinics throughout the country where hundreds of thousands of women congregate daily The initiative to exploit this opportunity should come from those responsible for the hospitals and clinics

At Soho Hospital for Women we are attempting to give advice on food and cooking to a minute fraction of this large group of the population We have been enabled and encouraged to make the experiment by the good offices of Dr B S Platt of the staff of the Medical Research Council and by the cooperation of the London County Council who have been so good as to give us the services of one of their expert advisers on domestic economy and cooking This lady comes to the outpatient department once a week, and having made a typical housewife's daily food purchases on the way demonstrates their uses and abuses This is not done in a formal lecture, which would prolong the outpatients' wait and discourage them, but in talks to a few patients at a time before or after they have been seen by me

The demonstrations are proving popular and the patients and their friends have expressed their gratitude for the service The secretary of the hospital will be very pleased to show the scheme in working to anyone who is interested and will communicate with him

London W 1	W C W NIXON

MEDICAL ASPECTS OF BOXING

SIR —Supposing that boxing has all the disadvantages claimed by Dr Jokl which I would not admit, the advantages obtained by it far outweigh them especially for men in the fighting forces These are courage, pugnacity endurance, activity, quick wittedness and general physical fitness Far more numerous and serious injuries are incurred in football I think Dr Jokl must have the anti-blood-sports mentality Of all the blood-sports boxing is certainly the bloodiest

Kimberworth, nr Rotherham	G E MOULD

ENURESIS

SIR —In your issue of Oct 18 Dr Greene gives us a somewhat turbid criticism of Mr Winsbury-White's valuable article on Enuresis This criticism cannot merit any serious reply if for no other reason than that he uses this quite senseless expression "It would be interesting to know how he *differentiates* these *apparently opposite* groups" in relation to two quite well-known and distinct classes of upper urinary tract dilatation which are clearly and reasonably explained in the author's text Further, he makes the dogmatic statement that Bartholin's glands do not open into the urethra I should be glad if he would produce for me any material evidence he has in his possession which proves this assertion

Guildford	DONALD MACLEOD

RADIOLOGY AS A CAREER

SIR,—I should like to endorse the remarks of "D M R E" That there is no shortage of radiologists is surely borne out by the fact that only about three advertisements for one have appeared since the beginning of the war, three offering a living wage at any rate It is pretty generally admitted that the future of radiology will be in the hands of full-time men in the hospitals Apparatus and running costs are so expensive that proper examinations will soon be prohibitive in private Yet there cannot be a dozen such appointments in Great Britain

The difficulties of radiology as a junior specialty, mentioned by your correspondent, are due mainly to the general staffs of hospitals who still think they know all about it and teach their students that all radiologists are bad They insist on having their work done as and when they wish, giving no chance of organisation to departments whose work is doubled and apparatus halved, and whose coat of arms should be Æsop's man and son and donkey Hospitals will have to face the facts and put in men at worth-while salaries and let them be masters in their own houses Otherwise there will be a shortage of good men, who will not take the present pay and status of technicians The scheme of subsidising half-trained men is typical of the present attitude and will ruin radiology for a generation

D M R

HYDATIDS IN BRITAIN —In referring to Dr Nicolson's paper of June 21 on a pelvic hydatid cyst and the annotation on peritoneal hydatids in the same issue Sir Louis Barnett writes from Hampden, New Zealand Hydatid disease is not so rare in Britain as many people think My personal investigations showed that practically all the large hospitals record a case or two every year, and the Registrar-General's mortality returns are not insignificant been actively concerned about problems of subnutrition at home In our colonies, which have been so generous to us, gross malnutrition is rife in peace as well as war

Parkstone, Dorset D FITZGERALD MOORE

STUDENTS ADVISE THE PRIME MINISTER

SIR,—As signatories of the telegram to which Sir Ernest Graham-Little refers in your issue of Oct 25, we fully realise that few have the knowledge to advise the Government on problems of pure strategy But surely everybody has the right to express his opinion on the general policy which he thinks the Government may be pursuing, or which he wishes it to pursue For the state of public opinion must be a consideration of some weight with the Government in coming to a decision, and the expression of such opinion is a democratic privilege which is not lost once the citizen's vote has been cast

ISAIAH MORRIS JUDY WATERLOW
CYRIL RUBEN

University College Hospital Medical School

SIR,—I trust that Sir E Graham-Little will not lay the flattering unction to his soul that he has disposed, by his letter in THE LANCET of Oct 25, of the 63 students who sent to him and to the Prime Minister the telegram urging more effective British intervention to help Russia In the first place his analogy of the surgeon performing an abdominal operation is far from convincing Unexpected conditions are assumed to be discovered on opening the abdomen which may make the completion of the operation immediately fatal The surgeon pauses, and the *implication is that he is pained and surprised* when the onlooking students call upon him, even shout at him, to do something Why shouldn't they? He gives no explanation to the students of his inactivity Does he expect them to remain indefinitely mute with acquiescence or admiration at his paralysis, which seems to them to be anything but masterly? After all, a pause from June 22 to the present date seems to be an exceptionally long time under the circumstances Perhaps also—leaving the analogy aside—some of the students have read Mr Lloyd George's "War Memoirs" and have developed a healthy scepticism about both politicians and military experts in consequence

Secondly, Sir Ernest seems to be unaware of the undemocratic tendency implicit in his argument If we are told to leave every decision to the "unfettered and consummate judgment" of any one person, this simply amounts to dictatorship On the other hand, criticism and discussion are the essence of democracy and if the authorities keep back important facts they must not be surprised if criticism falls short in certain respects They will, of course, in these circumstancesal ways be in a position to denounce such criticism as ill-informed—a useful dialectical weapon often used as a defence-mechanism, as shown by the extent to which they tend unnecessarily to hold back information even, in some cases, until after the enemy has published it

The 63 students are not the only people in this and other countries who are gravely concerned at our apparent failure to take more energetic action to help Russia, as Sir Ernest will know if he happens to read the papers There may be good, if obscure, reasons for this policy But I hope they are better reasons than those given in Sir E Graham-Little's letter

Harley Street, W 1 FREDERICK DILLON

EVALUATION OF NUTRITIONAL STATUS

SIR,—At the inaugural meeting of the Nutrition Society more time could perhaps have been profitably spent on discussing measurements of the growth-rate of children as an index of nutrition In a recent survey I examined 4000 children in different parts of Great Britain for signs of malnutrition, some both before and after dietary additions As a result I believe that in assessing the state of nutrition in children measurements of the rate of growth are still the most sensitive index Animal experiments strongly suggest that any dietary deficiency, or combination of deficiencies, will be revealed by a decrease in the rate of growth Conversely, in human feeding experiments in this country measurements of growth increments are the only observations that have plainly and unequivocally demonstrated the effects on children of an improved diet In using this nutritional yard-stick frequent measurements of he and weight over as long a period as possible should taken, single measurements are almost useless ther, it is essential to compare a child's growth cu with *contemporary* average curves, which should possible be optimum curves derived from the best fe groups in the population Alternatively, average heigh and weight tables from the recent reports of chief scho medical officers of the large cities may be used W know now that the stature of children is not a fix natural characteristic for a given age but may altered by varying the environment For exampl since 1920 the average height of 12-year-old Lee *elementary-school boys has increased by 2 in and th* weight by 7 lb

Assessing the nutritional state of adults is far mo difficult The epiphyses are fused and no longer m cubits be added to our stature Short of frank deficien disease we have to rely on a close examination of tho tissues which reveal signs of a defective diet most readi —the skin, mucous membranes eyes and blood The observations are not easy to make and their significan is sometimes disputed Perhaps the best index of t state of nutrition in groups of adults, in populations fr from frank deficiency disease, would be the changes incidence of chronic bacterial infection, especially of t respiratory system

The effect of certain other physiological systems whi exert a powerful but subtle influence on nutrition shou be borne in mind when assessing nutritional statu Abnormalities in the psychological system, especial anxiety, may prevent the proper utilisation of ingest food Disorder in the endocrine system—for exampl hyperthyroidism—may cause wasteful utilisation of foo Malnutrition may result from bad ventilation or excess fatigue owing to anoxæmia and lactic-acid accumulati interfering with cell nutrition Lastly, malnutriti may be due to unsuspected organic disease

I raise these points in order to re-emphasise the gre complexity of assessing the nutritional status and dieta requirements of man Although the great bulk malnutrition and deficiency disease can undoubtedly abolished by improving people's diets, there are certa additional factors which complicate the problem F practical, as distinct from experimental, purposes, think it would be of most value to concentrate o watching the growth curves of children and the resistanc to infection of adults as the surest indication of trends the nutritional status of the population

Royal Hospital, Sheffield JOHN PEMBERTON

BLAST INJURY OF THE LUNGS

SIR,—I am sorry that Dr O'Reilly and Dr Gloy have married their interesting account of blast injury the lungs (*Lancet*, Oct 11, p 423) by such a comple mis-statement of my "views" on the subject I ha never suggested that "blast injury is best marked in t phrenico-costal sinus" Their quotation (*Brit med* 1941, 1, 510) should be "Certain parts of the lungs a predisposed to injury Thus we find subpleural 'r markings,' injury in the phrenico-costal sinus regio and deep and posterior lesions in the region of t hilus" If they will refer to the *Lancet* of Aug (p 198) they will see this in diagrammatic form

I do not contend that "since they [i e blast injuri and contusions or crush injuries of the chest] are so oft found together they should be described together," b I do contend that absence of signs of violence to the che wall means little or nothing There may have been usual form of violence to the chest wall or a lorry weig ing 6 tons may have passed right over it, I have t conclusively proved with police photographs and pos mortem findings Conversely the presence of signs damage to the chest wall does not mean that lu lesions found are not wholly or in part due to blast have seen on a number of occasions how, especially elderly people with rigid chest walls, there may extensive fractures of ribs but no lung damage So f no real pathological or clinical distinction has bee shown to exist between cases of pulmonary concussi from (*a*) mechanical causes such as road accident (*b*) bomb explosions, and (*c*) depth-charge explosion &c One outstanding feature is the ease with which t lung lesions can be overlooked, either because they gi

cottish Conjoint Board

At recent examinations of the board of the Royal Colleges f Physicians and Surgeons of Edinburgh, and the Royal aculty of Physicians and Surgeons of Glasgow the following ere successful —

L.R.C.P. & S E, L.R.F.P. & S

C E V P Amerasinghe Benjamin Beck G C Cope, T V larke, Thomas Dean, A M A El Far, Yousif Faraony, Ralph riedman, A P. Gemmell M F El Giziri D F P Gordon, David ranet, Benjamin Greenberg, J H Haldane Margaret M Hanretty orman Hornstein, Dorothy L D Johnston, George Johnstone E Klein R I Kynaston, Henrietta Lennon, J K Lotinga H Lunine Herbert Macpherson O P Markandya, H J F itchell E K. Neidich, Jack O Hara, Valaydon Poonoosamy, H Reinsberg C B Robinson, Julius Schneiderman, Robert mith, Theodore Tuller

The following graduates of recognised foreign universities ave also been admitted licentiates —

Szulin Riterband, M D Rome, Else Wolfsohn M D Berlin

uberculosis Association

A meeting of this society will be held at 26, Portland Place ondon, W 1, on Saturday, Nov 8, at 10 30 A.M During the orning six short papers will be read and in the afternoon there ill be a discussion of problem cases and interesting radiograms

Medical Honour

Dr Donald Dunn, house-officer at the London Chest Hospital, has been awarded the M.B E Dr Dunn carried patients to safety single handed when the hospital was bombed

Royal Society of Medicine

A general meeting of the fellows of this society will be held at 1, Wimpole Street on Tuesday, Nov 4 at 3 30 P.M On Nov 5, at 2 30 P.M the section of surgery will meet to discuss streptococcal cross infection in wards The openers will be Prof A A Miles, Prof J Paterson Ross, Dr M van den Ende, and Colonel Leonard Colebrook At 3 P.M on the same day Prof A T Jurasz will read a paper to the section of history of medicine on the foundation of the Polish medical faculty within the University of Edinburgh On Nov 7, at 10 30 A.M, Mr F Watkyn-Thomas will deliver his presidential address to the section of otology He will speak on otitic meningitis Mr E D D Davis has chosen as the subject of his presidential address to the section of laryngology the problems of the otolaryngologist in war He will give it on the same day at 2 15 P.M, at 2 30 P.M Dr A D Marston as president of the section of anæsthetics will speak on the centenary of ether as an anæsthetic

Medical Casualties

Captain E J F Hinde, M.R C S., R.A.M C, has been reported missing at sea during September

In recent casualty lists the following R.A.M C officers were posted as prisoners of war T/Major J M. Fosbrooke, F.R C S E, W S/Captain J E S Carmichael, M.B Edin., W S/Captain A. Mikellides, and Lieutenant R M Solomon M.R C S

Cancer Research Studentship

The council of the Royal College of Surgeons will shortly nominate a Prophit student in cancer research. The studentship will not exceed an annual value of £500 with an allowance of £200 for travelling expenses and the appointment in the first instance will be for one year Applications should reach the secretary of the college, Lincoln's Inn Fields, W C 2 before Nov 22

CORRIGENDUM —The reference to Gurd, F B and McKim, L H on page 429 of Oct 11 should read *Amer J Surg* 1941, 51, 584

Appointments

BAILEY J SHACKLETON M.R.C S examining factory surgeon for Eye Suffolk.

BRAND, W G, M B Edin examining factory surgeon for Adlington Lancs

BUTTERWORTH, JOAN M B Lond D P H asst M O for Hants

GRIFFITHS, H J, M.R.C S, D P H temp asst M.O.H for Newport Mon

Births, Marriages and Deaths

BIRTHS

DESMOND —On Oct. 9 in Bermuda the wife of Surgeon Lieutenant A M Desmond, F R C S, R.N V R.—a daughter

DUNKERLEY —On Oct 20 at Westerham, Kent, the wife of Dr Arthur Dunkerley—a daughter

MATHESON —On Oct 20, in London, the wife of Mr Iain Matheson, F R.C S —a son

MONRO —On Oct 19 in Singapore, the wife of Prof J K. Monro, M Ch —a daughter

OLDFIELD —On Oct 21 at Harewood Leeds the wife of Major Michael Oldfield F R.C S R A.M C —a daughter

RICHARDS —On Oct 18 the wife of Dr A M. Richards, of Banbury Road, Oxford—a daughter

MARRIAGES

FLETCHER—SEELY —On Oct 24, at Winchester Charles Montague, M.R.C P, only son of the late Sir Walter Morley Fletcher to Louisa Seely

FRASER—BEETHAM —On Oct. 16 at Bermuda, Peter Kennedy Fraser M D Surgeon Lieut.-Commander, R N, to Doris Beetham

HARPER—SPILLER —On Oct 18 Curzon Harper, of Barking, to Violet Spiller M.D of Streatham

HART—MEYER.—On Oct 25, in London Philip D'Arcy Hart, M D to Ruth Meyer

HEWITT—WOOD —On Oct 25 at Watford Edward John Campbell Hewitt M D, R A.M C of Shenley, to Joan Millicent Wood.

DEATHS

ANDREW —On Oct 23 at St Austell Wilfrid Andrew, L M.S S.A

BENOLY —On Oct 22 at New Clips one Notts Nathaniel Benoly M D Würzburg L R C P formerly of Bethnal Green Road London aged 92

BRIDGES —On Oct 22 in Cheltenham Arthur Brodie Hamilton Bridges, O B E, M R C S, major, R A.M.C, late of Kilmington, Devon

REDFERN —On Oct. 23, at Compton Winchester John Joseph Redfern M D Belf aged 80

WARD —On Oct 23 at Bournemouth, John Alfred Ward, M.D Durh, aged 77

Obituary

H E G BOYLE

O B E, F R C S, D A

Henry Edmund Gaskin Boyle was born in Barbados and was educated at Harrison College there before coming to England where he qualified from St Bartholomew's Hospital in 1901 While a student he was president of the Abernethian Society and after qualification he held the post of casualty officer at the Bristol Royal Infirmary He then returned to Bart's as junior resident anæsthetist, rising in due course to be head of the department When he began his life's work the "rag and bottle" methods were universal, but about 1912 the work of Hewitt in this country and Boothby and Cotton in America put gas-and-oxygen on the map and Boyle was quick to grasp its possibilities In the last war he was instrumental in getting the army authorities to realise the importance of the new anæsthesia in shocked patients and the dispatch of his portable apparatus to casualty clearing stations in France undoubtedly saved many lives For these services he was made O B E Boyle made a visit to the United States to see for himself the progress of anæsthetic technique While there he was struck by the value of the Davis gag for dissection tonsillectomy, and on his return he introduced it to British ear nose and throat surgeons He was also one of the pioneers of intratracheal anæsthesia In 1935 the Royal College of Surgeons elected him a fellow and in the same year he received the new diploma in anæsthetics He was one of the first pair of examiners for this diploma and his fairness and acceptability were widely acknowledged

For over 40 years "Cockie" Boyle could be seen nearly every day at Bart's and the number of students who benefited by his practical teaching was enormous He also held anæsthetic appointments at Paddington Green Children's Hospital and St Andrew's Hospital, Dollis Hill, and had a large private practice He was not a ready writer, but he contributed now and then to the medical papers and published with his colleague Mr C Langton Hewer "Practical Anæsthetics" which reached a third edition

Boyle was by nature extremely kind and he had hosts of friends "To an anæsthetist who met him only outside hospital, the characteristics which most impressed me in him," J B writes, "were his joviality, a slightly sardonic sense of humour, readiness to speak at a meeting, and general level-headedness Boyle's earliness in the field with an efficient and not too complicated gas-and-oxygen machine, in the days when that form of anæsthesia was rapidly being established after the last war, has earned for him a lasting name among the anæsthetists" He took a deep interest in student activities, and was a familiar figure in the stand at Richmond for the rugger cup ties His own sport was cricket and he often displayed his skill in the matches between past and present Bart's men

In 1910 he married Mildred Ethel, daughter of J W Wildy and widow of Mr Leslie Green, F R I B A His health had been failing for some years and he died on Oct 15, aged 66

DAVID ORR

M D EDIN

THE sudden death of Dr David Orr on Oct 8 at his home in Edinburgh came as a shock to his friends, for he had just returned from a holiday and seemed to be in good health David Orr was born in 1872 and educated in Edinburgh at George Watson's College He qualified in 1894 from the university, and in 1902 was specially commended for his M D thesis After qualifying he studied diseases of the eye in London at Moorfields Hospital, and for a time was clinical assistant in the ophthalmic wards of the Edinburgh Royal Infirmary From postgraduate studies at Heidelberg and Vienna he returned to Scotland to work with Clouston at Morningside, then at Melrose Asylum, and later he held the post of assistant pathologist to the laboratory of the Scottish asylums In 1898 he was appointed assistant medical officer and pathologist to the Prestwich Asylum, Manchester, and was promoted deputy superintendent in 1911 and medical superintendent in 1924 Unfortunately his health broke down the following year, and he retired to Edinburgh, where he resumed his research in the laboratory of the Royal College of Physicians

Orr was an indefatigable worker, and during his time as pathologist at Prestwich he published important papers dealing with the pathology of acute insanity, the influence of toxins on the central nervous system, and the paths of infection through the lymph-stream in the spinal cord He was familiar with the German, French and Italian literature of his subject, and visited the continental clinics and laboratories In 1909 with R G Rows he published a translation of Lugaro's "Modern Problems in Psychiatry" No-one who worked with him will forget his vivid personality and buoyant enthusiasm He carried with him "the infection of a good courage" and so could "meet all life's ills and accidents with gallant and high-hearted happiness" His main interests outside his work were golf and music He sang well and had a fund of good stories, and an evening in his hospitable home was something to be remembered

He leaves a widow and two daughters

HASTINGS GILFORD

F R C S

Mr Hastings Gilford died at the age of 80 on Sept 6 in Reading where he had set up in practice in 1887 soon after qualifying from Guy's He continued to practise as a general practitioner to the end of his life and many families recognised his skill as an accoucheur and his devotion to children But his consulting practice, both medical and surgical, was also growing—he had taken his fellowship in 1889—and in due course he became surgeon to the Reading Dispensary and during the last war to the Sutherland Hospital for Pensioners With his seeking mind it was inevitable that he should gravitate to the Reading Pathological Society and he read many papers at their meetings Though most of his contributions were surgical he was a pioneer in the study of the ductless glands and his classic paper on progeria was published in our columns (1914, 1, 672) These investigations led him to the study of cancer, and most of his later writings were a challenge to experimental research, for he contended that cancer was not caused by an outside agency acting on the cells but by a disorder of the cells themselves stimulated by civilised man's unnatural ways of living In "Postnatal Growth and Development," published in 1911, he put forward the thesis that development begins with the integration of the cell, which continues with increasing complexity and diminishing impetus up to middle age, then merging into declining phases in which this process is reversed His Hunterian lectures in 1913 dealt with the nature of old age and cancer from this standpoint He continued his studies of the biological and clinical aspects of the subject and "Tumours and Cancer" appeared in 1925, and he also contributed forceful letters to our columns Later under the name of John Cope he set out his views for a wider circle of readers With this bias towards distrust of the conventional Hastings Gilford combined a disarming humility and a receptiveness to the lessons of experience that made him good company for young and old He took much from the town of his adoption and gave more in return

Gilbert Adams Reading

MR G STAFFORD ALLEN, who died suddenly in London on Oct 22, aged 70, was partner in Stafford Allen and Smith Ltd of Long Melford, Suffolk, medicinal herb growers Interest in herbs and gardens was traditional in the Quaker family to which he belonged and he was equally at home in fruit-growing, agriculture and pedigree pig breeding, while his hobby was the rock garden He was a trustee and manager of the Ogilvie school of recovery at Clacton

RENAL LESIONS IN TWO CASES OF CRUSH SYNDROME

J SHAW DUNN, M D GLASG , M SC MANC
PROFESSOR OF PATHOLOGY, UNIVERSITY OF GLASGOW

MARJORIE GILLESPIE, M D GLASG
ASSISTANT PATHOLOGIST TO THE LONDON COUNTY COUNCIL

J S F NIVEN, M D GLASG
LECTURER IN PATHOLOGY, UNIVERSITY OF GLASGOW

(*Pathological Department, University and Western Infirmary, Glasgow, and L C C Group Laboratory, Hampstead*)

FROM the accounts of the sequelæ of certain forms of crushing injury recorded by Bywaters and Beall (1941), Beall, Bywaters, Belsey and Miles (1941), Mayon-White and Solandt (1941), and others, it is clear that in such cases acute renal insufficiency is relatively frequent While this is accompanied by certain pathological changes in the kidneys, the descriptions of the renal pathology so far available do not appear to offer a completely satisfactory explanation of the gross functional disturbances observed during life Neither do they seem sufficient to provide a clear correlation of this with any previously described form of acute renal lesion In two cases of this kind which we have recently had the opportunity to examine the changes in the kidneys are of a definite and unusual nature We hope that our findings may stimulate inquiry as to whether similar appearances can be detected in the kidneys of other fatal cases of crush syndrome

CASE 1

A woman, aged 18, was admitted as an air-raid casualty to the Hampstead General and N W London Hospital, on April 17, 1941, under the care of Mr Arthur Gray, F R C S She had been pinned under a beam for six hours On admission she was in a state of shock with cold extremities, and the blood pressure was 112/78 mm Hg Both legs had been crushed under debris and there was an area of bruising on the left calf with death of a portion of skin, measuring 5 × 5 in There were also many abrasions of the skin and a fracture of the pelvis was recognised by X rays Steps were taken to counteract shock and the wounds were cleaned and treated with sulphanilamide powder and flavine , 2000 units of A T S was administered intramuscularly The patient received also potassium citrate gr 30 and sulphapyridine 1 g three times a day During the following days the pulse continued poor though the blood pressure had risen There was restlessness and drowsiness without sleeping and vomiting was frequent Some of the daily observations are recorded in the table Œdema appeared in the legs, particularly in the right thigh, on the second day , it increased and became gross on both sides before death Hiccough developed on the sixth day and acute dilatation of the stomach on the seventh , the dilatation was relieved by lavage The pulse became variable, with dropped beats, and the patient died on the ninth day

Observations in case 1

Day	Blood pressure	Fluid intake	Vomiting	Urinary output	Urine	Urinary urea	Blood urea	Hæmoglobin
	mm Hg	c cm				mg/100 c c m		%
1			+	420				
2		1530	+	240	Blood +			
3	140/90	1080	+	120 +	Blood +			
4	145/90	900	+	240 +				
	136/85	510	+	180	Red cells in deposit			
6	165/85	3630	1770	240	Alb +, red cells + granular casts + +		106	85
7	158/80	3600	3720	270	Alb + red cells + granular casts +			
8	165/80	3000	610	420	Tr alb , no blood		200	83
9	130/68				No blood or alb	1000	368	

An *autopsy* was performed (M G) on April 26, twenty-three hours after death There were numerous skin abrasions and the injuries previously mentioned were confirmed A circumscribed area of pale necrosis 6 cm long was found in the right quadriceps femoris muscle Œdema was present in both legs and in the chest wall The heart showed no important change Petechiæ were present in the pericardium and pleuræ The pleural cavities each contained 1500 c cm of clear fluid , both lungs were grossly œdematous No important change was seen in other organs apart from the kidneys These were enlarged (R 242, L 230 g) The capsules were non adherent and the surfaces smooth On section fluid oozed from the cut surfaces The renal cortex was pale and mottled, and in the deep parts there was an opaque whitish zone 2 mm in breadth surrounding the bases of the medullary pyramids, which were darkly congested

Histological examination of the kidneys shows that the general arrangement of the cortex is not disturbed by any antecedent chronic change There is a slight separation of the tubules as by œdema The glomeruli are normal in size, cellularity and blood content Spheroidal masses of homogeneous material, somewhat resembling dead cell bodies, occur in many of the capsules of Bowman , these appear to be albuminous aggregates, for the lining cells of the capsules are, in general, in situ and normal In the *first convoluted tubules* the epithelium is of normal appearance , there is no catarrh or evidence of recent regeneration, while with special stains neither fat nor hyaline droplets are demonstrable Their lumina, sometimes very slightly dilated, contain amorphous debris or rounded masses like those in the capsules , no hæmorrhages or casts are seen in them The *second convoluted tubules* are more conspicuous than normally owing to denser nuclear staining All of them show some pathological change, though the degree of this varies greatly In the majority the alterations are slight, comprising moderate dilatation of lumina, slight basophilia of cell protoplasm and increase in the number and density of staining of nuclei These appearances, which correspond to those seen in regenerated tubules after a mild experimental tubular nephritis, are more pronounced in occasional tubules or in small groups of segments where mitoses can be recognised in the cells around such tubules there is definite plastic overgrowth of the supporting interstitial tissue (fig 1) In many of these second convoluted tubules there are also light casts of orange brown material resembling hæmoglobin which takes the form of beaded filaments or amorphous masses In one or two places in the cortex there are foci of still more severe damage of second convoluted tubules of a type which will be described in the boundary zone where they occur in much larger numbers (fig 2) *Boundary zone* It is in this region, where the straight descending limbs of first convoluted tubules in the medullary rays of the cortex are changing to narrow descending limbs of Henle, that the most remarkable histological picture is observed In any single section the low power reveals large numbers of severe focal lesions affecting the broad ascending limbs of Henle's loops, the segments which lead up to the second convoluted tubules in the cortex (fig 3) These lesions often occur in groups and each group is surrounded by a very definite recent overgrowth of interstitial tissue By examination of serial sections it is in most instances easy to ascertain that each focus implicates not only a tubule but also the thin wall of an adjacent venule The tubule can be traced from comparatively normal conditions above and below to a level where there occurs an aneurysmal bulge of 40–80 μ diameter This is usually filled by a dense mass of albuminous coagulum which stains faintly with eosin and gives a light fibrin reaction The epithelium lining the bulge has suffered especially severe damage and the actively regenerating cells are often thinned out and flattened, the relining being sometimes incomplete This bulging part of the tubule indents the wall of the small venule and often protrudes into the lumen of the latter, while in some instances there is clear evidence that it has actually ruptured through (fig 4) The inner wall of the venule at a point of rupture is covered by a cap of thrombus continuous with the coagulum in the tubule, and frequently a strand of proliferated epithelium is enclosed in the thrombus. Sometimes a considerable strand of proliferated cells extends in the venous channel loosely held in thrombus These proliferating cells in this unusual site can be identified with considerable

Notes, Comments and Abstracts

HABITUALLY AND FOR GAIN

L Farrer Brown, B SC (ECON) LOND
BARRISTER AT LAW

THE innocent looking phrase "habitually and for gain" has made its reappearance in connexion with a proposal that unqualified persons should be prohibited from making nursing their livelihood The midwifery profession had experience of the phrase from 1910 to 1926 Accounts of that experience appeared at the time in annual reports of the Central Midwives Board and of medical officers of health, but a brief recital may be of interest

The Midwives Act 1902 (section 1 (2)) provided that from April 1, 1910 (which was about 7 years after the Roll of Midwives had been established), no woman should "habitually and for gain attend women in childbirth otherwise than under the direction of a qualified medical practitioner" unless she was certified as a midwife Exemption was granted to legally qualified medical practitioners and to "anyone rendering assistance in a case of emergency" Any woman who offended against this provision was liable on conviction before a court of summary jurisdiction to a fine not exceeding £10

A considerable number of prosecutions were undertaken in different parts of the country and fines of varying amounts were imposed on offenders, but in many cases in which there appeared to be a clear breach of the law the matter was not brought into court or the prosecution was unsuccessful because of the loopholes open to a defendant For a prosecution to be successful five things had to be proved

(1) that the defendant was not a certified midwife,

(2) that she had attended habitually,

(3) that she had attended for gain,

(4) that she attended otherwise than under the direction of a doctor, and

(5) that her attendance was not the rendering of assistance in a case of emergency

Proof of the first was easy, but the remaining four often presented difficulties Many magistrates required strict proof that attendance had been habitual and for gain "Habitually" is an elastic term and was a hard thing to prove because evidence was required of attendance under improper conditions in a number of cases and within a recent period "For gain" is ambiguous If payment is not demanded but a present is given as a thank-offering is that gain? Even when the payment of money could be proved, evidence that the defendant had rendered other services at the same time, such as washing clothes, cooking, helping in the house, or looking after the other children in the family, tended to weaken the prosecution's case To prove the payment of money was not without its difficulties For example, the mother states on oath that she called at the defendant's house and paid the defendant's fee for attending at the confinement, but was not given a receipt The defendant denies having received any payment and declares that she attended the mother merely as a friend There is a conflict of statements and in the absence of a witness or a receipt signed by the defendant the charge is likely to be dismissed on the ground that there is no evidence corroborating the mother's statement

"Covering" by medical practitioners provided some offenders with the means of escaping punishment At one stage such covering was by no means infrequent, and the Central Midwives Board therefore brought proceedings against certain doctors before the General Medical Council The first of these cases was in respect of covering in its most open and common form The doctor had arranged with an uncertified woman to "look after" her cases for her "at the modified fee of 7*s* 6*d*" It was proved that three women had been delivered by the uncertified woman, that the doctor had called the next day but not subsequently, that he had not examined the patients, and that he had been paid a fee of 7*s* 6*d* by the uncertified woman in each case He had notified the births—a proceeding clearly designed to conceal that the women had been delivered by the uncertified woman alone The doctor was found guilty by the General Medical Council

The exemption granted to anyone rendering assistance in an emergency was abused This abuse seems to have been facilitated by the attitude of some benches of magistrates and by the desire of many patients to screen the uncertified women who had attended them In one case in the home counties the defendant pleaded guilty, but said that she wished to continue her work as a midwife in the interests of the poor of the neighbourhood Apparently the sympathies of the women she had attended in their confinements, of the magistrates and of the general public present at the hearing were enlisted on her behalf The chairman of the bench stated that they were bound to record a conviction but did so with very great regret, that they would reduce all the defendant's expenses and would only impose a fine of 1s which would be paid by one of the members of the bench The chairman then informed the defendant that in future she could act in the absence of a doctor only when the case was one of emergency, to which she replied "There will be plenty of emergency cases then," and the chairman responded "*We know you are doing a good work*"

A change in the law was made in 1926 The phrase "habitually and for gain" was dropped, and an attempt was made to prevent abuse of the necessary exemption in a case of emergency by placing on the defendant the onus of proving that attention had been given "in a case of sudden or urgent necessity" The new provision,[1] which is still in force, was in the following terms

> "If any person, being either a male person or a woman not certified under this act, attends a woman in childbirth otherwise than under the direction and personal supervision of a duly qualified medical practitioner, that person shall, unless he or she satisfies the court that the attention was given in a case of sudden or urgent necessity, be liable on summary conviction to a fine not exceeding ten pounds"

Exemption was granted to pupil-midwives and medical students attending confinements as part of their training It will be noted that a curious omission in the earlier act was remedied In the 1902 Act the prohibition applied only to unqualified *women* In 1926 unqualified men-midwives were brought within the scope of the prohibition

---

BRITISH COLLOIDS LTD (Crookes Laboratories) have withdrawn the following lotions and creams from the general market Lacto-calamine, calamine cream and lotion, zinc cream, and mercury and sulphur scalp lotion These preparations will in future only be supplied on a doctor's prescription

Infectious Disease in England and Wales

WEEK ENDED OCT 18

Notifications—The following cases of infectious disease were notified during the week smallpox 0, scarlet fever, 1195, whooping-cough, 1979, diphtheria, 1002, paratyphoid, 62, typhoid, 16, measles (excluding rubella), 783, pneumonia (primary or influenzal), 624, puerperal pyrexia, 161, cerebrospinal fever, 107, poliomyelitis, 50, polio-encephalitis, 2, encephalitis lethargica, 4, dysentery, 143, ophthalmia neonatorum, 86 No case of cholera, plague or typhus fever was notified during the week

The number of civilian and service sick in the Infectious Hospitals of the London County Council on Oct 15 was 1295, including scarlet fever, 168 diphtheria, 267, measles, 19, whooping cough, 530, enteritis 24, chicken pox, 17 erysipelas, 25, mumps, 9 poliomyelitis, 6, dysentery, 17, cerebrospinal fever 14, puerperal sepsis, 14, enteric fevers, 46, german measles, 2, other diseases (non infectious) 56 not yet diagnosed 81

Deaths—In 126 great towns there was 1 (1) death from enteric fevers, 2 (0) from scarlet fever, 1 (0) from measles, 10 (4) from whooping-cough, 11 (1) from diphtheria, 46 (0) from diarrhœa and enteritis under 2 years, and 12 (0) from influenza The figures in parentheses are those for London itself

Sheffield reported 8 deaths from diarrhœa, Birmingham 7, and Manchester 6 In the same week Dublin had 22 fatal cases of diarrhœa and Glasgow 15

The number of stillbirths notified during the week was 180 (corresponding to a rate of 33 per thousand total births), including 18 in London

nephritis in man and has been a characteristic finding in experimental tubular nephritis in animals (Dunn, Howarth and Jones 1924)

The most comprehensive descriptions of tubular epithelial changes so far available are by Bywaters and Beall, who mention severe damage in the form of fraying of protoplasm and vacuolation, but also regenerative changes with mitotic division and proliferation These are referred to ascending limbs of Henle and to convoluted tubules generally Mayon-White and Solandt have noted degenerative changes of acute character with pyknosis of nuclei, but mention no special localisation Minami (1923) who, as has been pointed out by Bywaters (1941), gave an account of the renal lesions in cases of similar character, also described only acute changes in convoluted tubules without specific localisation In our own cases the definite epithelial alterations appear to be restricted to ascending limbs of Henle and to second convoluted tubules, and are at a proliferative and healing stage, as might be expected in tubular lesions of over a week's duration The identification of the two sets of convoluted tubules in a previously normal kidney is not difficult Apart from having a wider diameter and taller epithelium, each first tubule forms a compact mass of closely packed convolutions into which no other tubule enters The second, with narrower calibre, lower epithelium and closer set nuclei, is much shorter and pursues an open angled course between the above masses, it therefore appears in sections only as isolated rings or ovals or in small rather loose groups The ascending limbs of Henle which lead to the second tubules are, it may be noted, somewhat similar to these in histological appearance While the anatomical structure and arrangement of the nephrons are now fairly fully established, much as yet to be learned about the functioning of the different parts, but there is increasing evidence that it is in the lower segments that final adjustment of reaction occurs, in man and carnivora as a rule to the acid side.

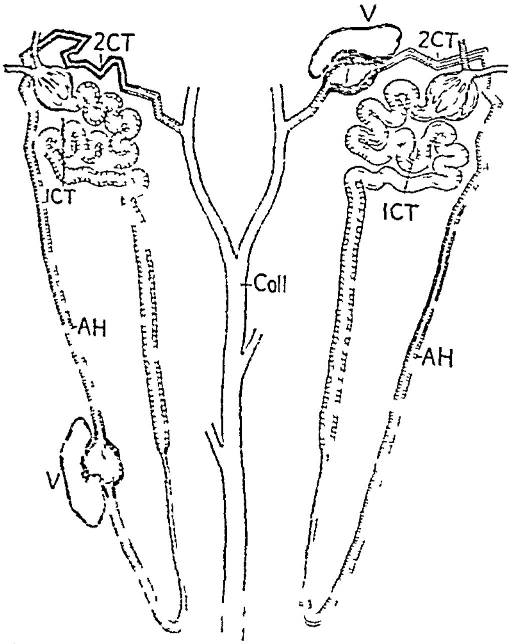

FIG 2—Arrangement of nephrons showing sites of lesions I C T 2 C T = first and second convoluted tubules A H = ascending limbs of Henle's loops Coll = collecting tubules V = venules with severe tubulo venous lesions

It is difficult to find in the diseases of man any analogy for a condition of acute selective damage of the lower segments of the nephron, but evidence drawn from experimental lesions in animals may assist in elucidating the pathogenesis of a lesion of this kind Dunn and Polson (1926) have shown that by the introduction into the circulation of the rabbit of large doses of uric acid in solution, in the form of lithium monourate, severe selective damage can be produced in the ascending limbs of Henle, second tubules and to some extent collecting tubules, while the first convoluted tubules remain normal in appearance Necrosis of the epithelial linings is produced within an hour or so of the injection, and regenerative changes are in full swing by the fourth to eighth day In the regenerative phase the lesions show distinct similarity to those in the present cases, except that tubulo-venous lesions are not found In these animals, just as in uranium or oxalate nephritis where the first convoluted tubules are selectively damaged, there is anuria or oliguria with low urea concentration, and the blood-urea rises These phenomena have been attributed by Dunn and Polson to non-selective reabsorption of filtrate through the damaged walls of tubules into the blood, thus escaping excretion More recently McFarlane (1941) has shown that in the experimental phosphate nephritis of rats, which was described by Mackay and Oliver (1935) and by Duguid (1936), the

certainty as epithelial, the endothelium of the vessel is unaltered except where it has been completely destroyed under the cap of thrombus In many of the smaller foci of this type the albuminous mass protrudes through a gap in the dilated wall of the tubule into the connective tissue outside, and it is not clearly ascertainable that it has entered a venule, though the appearances leave it possible that a very small vessel has been involved The number of these foci of intense tubular damage is in this case very large, so that in a single low-power field it may be possible to identify three to five involving the wall of one of the larger venules of 200 μ diameter (fig 5) *Medulla* Most of the collecting tubules are normal but in a number of them there are orange brown casts of varying size These are mostly light and are composed of beaded ribbons of material resembling hæmoglobin A few are more solid and are large enough to press on the epithelial lining, which is then flattened and may show some regenerative change The evidence of damage of cells is, however, comparatively slight in any of the collecting tubules

CASE 2

A man, aged 51, admitted to hospital on April 17, 1941, was an air raid casualty who had been buried under debris for 8 hours He had crushing injuries of the legs with fracture of the right internal malleolus and laceration of muscles in the right foot The clinical course was characterised by oliguria and hæmaturia, and the blood urea rose from 100 mg per 100 c cm on April 21 to 384 mg on the 24th and 400 mg before his death on the 25th On the 24th the urinary urea was 1 3 g per 100 c cm and chlorides 1 5 g as NaCl per litre The illness was similar to that in case 1

Autopsy—There was no obvious œdema of subcutaneous tissues The heart showed slight dilatation of the right ventricle Both lungs had areas of consolidation in the lower lobes with suppurative softening and there was pleurisy on both sides The kidneys (R 180, L 210 g) were large and of firm fleshy consistence, not fibrous The surfaces were slightly granular and there were a few small areas of indentation of irregular shape On section the cortex was of normal width and aspect, apart from some congestion The pyramids were congested

Histological examination—There are in the renal cortex a considerable number of ill defined areas of partial atrophy of tubules with sclerosis of a few glomeruli, and around these there is some interstitial thickening with lymphocytic infiltration In the medulla also some vertical bands of moderate fibrosis occur These changes, which may have been pyelonephritic in origin, are clearly of old standing and in keeping with this there is some diffuse intimal thickening in arteries and arterioles There remain, however, considerable areas of cortex which have been practically normal, and in these parts there can be recognised lesions of recent date similar to those described in case 1 These lesions comprise the following (*a*) Light brown casts resembling hæmoglobin in second convoluted tubules (*b*) Proliferation of cells in some of these tubules (*c*) The more intense focal lesions with rupture of tubules and extrusion of albuminous material The majority of these are of small size and cannot be seen to enter venules, most of them occur in the boundary zone A few of them, however, are larger and implicate the walls of venules as in case 1 The walls of the venules are thicker in this case and may have been less easily perforated The lesions here appear to be slightly older and more nearly healed than in case 1 (*d*) In the medulla large orange brown casts occur in many collecting tubules and their presence is associated with some appearance of damage and regeneration of epithelium The casts are more numerous than in case 1

DISCUSSION

In the records of fatal cases of crush syndrome the brown casts in the renal tubules have been a conspicuous feature, and similar casts have been described in the urine of cases which recovered (Longland and Murray 1941) The question has been raised whether blockage of tubules by these casts could be the cause of the renal disability, but histological evidence on this point is inconclusive The persistence of casts in the tubules could so easily depend on diminution of filtrate, whether this resulted from an impaired circulation or from some other cause The most important criticism of the blockage theory, however, has been made by Bywaters and Beall, who point out that if tubular obstruction alone were concerned such urine as was secreted should theoretically be of normal composition, coming from unobstructed tubules, but in their experience the urine was little more than a glomerular filtrate (urea-concentration factor 1 6–2 8 in their cases 1 and 2), and this is confirmed by figures taken from Henderson's (1941) chart of a recovered case (concentration factor about 3 3 on the tenth day when the urinary output was about 700 c cm) In our cases 1 and 2 also single observations on the eighth day gave concentration factors of only 2 7 and 3 3 respectively Such extreme degrees of ablation of one of the highest functions of the kidney are of considerable moment and it is no doubt significant that among acute renal conditions the greatest reduction of concentrating power is known to occur when there is severe damage of tubular epithelium This may be observed in mercurial

The temperature remained subnormal except in the terminal phase of the two fatal cases. There were no rigors, and no patient complained of chills. The pulse-rate was variable, but was usually about 80 per min. in most patients. The absence of fever and rigors is one of the main differential points between this condition and catarrhal jaundice.

The urine contained bile-pigments in all cases, and there was albuminuria at some period in four patients. Webster's test[1] demonstrated the excretion of trinitrotoluene in the urine but was not constantly positive in all patients, only becoming so during treatment in some cases. Many of the workers in trinitrotoluene give a positive Webster test; this indicates not intoxication but only excretion of the substance. Leucine and tyrosine crystals were not demonstrated in the urine of any patients.

The blood in all cases gave a positive direct and indirect van den Bergh reaction. No constant changes could be demonstrated spectroscopically, because owing to enemy action adequate facilities were not available. Anæmia was only severe in one patient who developed aplastic anæmia after the jaundice had resolved. The white-cell count showed a leucocytosis of up to 15,000, with relative polymorphonuclear increase in several patients (this has been observed in some apparently normal workers).

The lævulose-tolerance test was performed as a routine during convalescence, but showed no abnormality in any of the cases which reached this stage.

No evidence of the presence or formation of gall-stones was found at any stage.

AUTOPSY FINDINGS

Two patients have died, one from acute liver atrophy 16 days after the appearance of jaundice, the other from aplastic anæmia 18 weeks after the onset of jaundice and 9 weeks after its disappearance.

The findings in the first case were those of acute yellow atrophy of the liver. There was extensive jaundice, with many ecchymoses and petechial hæmorrhages on all serous membranes. The liver was grossly shrunken, soft and bile-stained, and weighed only 21 oz.; the appearances were those of the necrotic stage of acute yellow atrophy. The spleen showed some softening but was otherwise normal. The bone marrow was red in the whole length of the right femur. The kidneys showed poor differentiation of medulla from cortex (possibly partly post mortem change). Other organs showed no gross abnormality apart from bile staining. Sections showed gross necrosis and disorganisation of the liver lobules, with some infiltration with round cells, and much amorphous debris, presumably from broken-down liver cells. The bile ducts were not much affected, and did not show any inflammatory or hyperplastic changes.

The second fatal case was of special interest, for the jaundice had resolved completely 9 weeks before the patient died of aplastic anæmia, of which there was no sign while the jaundice was present. The post mortem appearances were as follows. Pallor of the skin and some ecchymoses. The fauces and soft palate were ulcerated. The liver was finely granular and somewhat shrunken. The cut surface of the liver showed some pale areas of degenerating liver tissue, and pink areas of developing fibrosis. It weighed 40 oz. The spleen and kidneys showed no gross abnormality. The marrow of two ribs, the sternum, lumbar vertebræ and upper halves of both femurs was reddish, but not as red as typical hyperplastic marrow. Other organs showed no gross abnormality. Sections showed subacute necrosis of the liver, with some fatty degeneration, hypertrophy and fibrosis. Marrow smears showed no evidence of myelocytes or nucleated red cells.

CLINICAL COURSE AND TREATMENT

The patients must be removed from contact with trinitrotoluene as soon as the condition is suspected, and put at rest. On admission to hospital all the patients except one were given 20 g. of glucose daily in drinks and 15 units of insulin per day; in this one case the jaundice persisted for 2 months—about a fortnight longer than the average period for the others. Vitamin C 100 mg. was given daily by mouth. A light diet was given and symptomatic treatment ordered as required. It should be remembered that many drugs—e.g., sulphonamides, chloral hydrate and amidopyrine—may cause damage to the liver or bone-marrow, and so are to be avoided in T N T poisoning. The jaundice in several cases increased after admission to hospital, but began to fade after 1–2 weeks, and in four cases was gone within 6 weeks; one other resolved after 8 weeks, and a second resolved slowly about 3 months after the onset.

The true end-results of the condition in these patients cannot yet be estimated, for it is only 6 months since the first patient became jaundiced. The present condition of all the patients may be summarised thus:

One patient has died of acute yellow atrophy (case 1).

One patient developed agranulocytic angina with the blood-picture of aplastic anæmia, and in spite of all treatment died 14 days after readmission (case 2).

One patient has ascites, apparently from cirrhosis, but is now free from jaundice, and the effusion has to be tapped only at increasing intervals (case 3).

Four patients have apparently recovered and are free from all symptoms.

The final result of the four apparent recoveries and the patient with cirrhosis can only be judged when further time has elapsed and liver-function tests have been carried out. The findings in the liver of the second fatal case seem to indicate that a good deal of regeneration of liver tissue can take place, and probably has taken place in the apparent recoveries.

CASE-RECORDS

CASE 1.—*Unmarried woman, aged 21, started work at ordnance factory in March, 1941.* On July 9 she was admitted to hospital complaining of jaundice, noticed for about 4 weeks; on July 5 she had felt pain in the epigastrium, and had vomited next day. The bowels were regular, but pale stools were noticed about July 5. *On admission* there was a fairly well-marked yellow jaundice, with clean moist tongue, and normal temperature and pulse-rate; the urine contained bile pigments, but no other abnormal constituent. Van den Bergh reaction, positive direct and indirect. Webster test on the urine became positive on July 14 and a faint trace of albumin appeared in the urine on July 17. The blood picture was normal. On the 19th the jaundice was deeper, and the patient was rather dazed, with poor pulse and persistent vomiting. Intravenous glucose saline drip was instituted, but her condition deteriorated. On the 21st petechiæ and ecchymoses appeared, and the liver dullness was decreased. The patient died on July 23 with high terminal pyrexia.

CASE 2.—*Unmarried woman, aged 35, started work with T N T on March 10.* On the 31st she noticed nausea, succeeded a day or two later by vomiting; epigastric discomfort and jaundice appeared on April 6. She was admitted to hospital on April 12. There was well marked jaundice, with bile pigments in the urine and pale stools. Constipation was not noted. The temperature and pulse were normal, and no other abnormalities were found. At this time blood examination revealed 5% reticulocytes and no anæmia. The jaundice became extremely deep about May 5 and then faded. A trace of albumin was found in the urine at this time. On June 7 the patient was symptom-free, with no jaundice and a normal lævulose-tolerance test. She was discharged from hospital and went away on holiday.

On Aug. 2 she returned from holiday and was readmitted complaining of sore throat and petechial rash. Blood examination revealed agranulocytosis and aplastic anæmia, which were the cause of her ulcerated throat. The temperature fluctuated about 101° F. and the pulse rate about 110 per min. Daily transfusions of fresh blood, with intramuscular liver extract and pentnucleotide daily failed to influence the condition, and she died on Aug. 16. During this *second period in hospital* there was no jaundice.

CASE 3.—*Married woman, aged 42, with history of three normal pregnancies. Started work at factory on Feb. 7, 1941.* On April 20 she vomited and noticed dark urine; next day she noticed a tinge of jaundice and felt vague epigastric pain. She was admitted to hospital on April 25 with mild jaundice. The temperature and pulse rate were subnormal and remained so. The liver was not palpable, but there was slight tenderness on pressure in the right subcostal region. The urine contained a trace of bile pigments and the blood van den Bergh test was positive both direct and indirect. No other abnormality was detected. The jaundice persisted and the patient vomited once after admission. On

lesion is again almost restricted to the lower nephron segments, and he agrees with Dunn and Polson in attributing the special localisation of lesions at this level to change of reaction in the filtrate, added no doubt to increase of concentration which has been effected at higher levels.

A feature which appears to be unique among the tubular changes in the present cases is the localisation of the most intense damage at points where the lower nephron segments lie in close proximity to veins. Further confirmation of this occurrence in other cases would be desirable but in our material the frequency of the association is so remarkable as to suggest a definite causal nexus. In uric-acid nephritis there seems to be little doubt that the lesion is determined by precipitation of the agent from a soluble form in which it is relatively harmless to a solid which exerts the destructive effect. It seems possible that in the present cases also a substance of special toxicity is produced in the presence of acid, and that the proximity of venous blood has an influence in permitting a greater swing towards an acid reaction in this area than is reached at other parts.

Nothing certain is known as yet of the nature or source of any toxic agent which may be responsible for the renal damage in cases of crush syndrome. The available facts, however, appear to justify the primary view to which most observers have adhered—that after release of the affected tissue from a compressed and more or less ischæmic state something toxic is absorbed from it into the circulation as the vessels reopen, and that the toxic agent affects the kidney in the course of excretion. The number and kinds of possible toxic agents which could so arise is conjectural and the suggestion that the cast material, which apparently contains myohæmoglobin (Bywaters and Delory 1941), is toxic is not to be ignored. Some light will probably be thrown on the genesis of this condition by experimentation with products obtained from muscle or other tissues. While not attempting to prejudge the results of this investigation, we suggest that both uric acid and phosphoric acid may well come under review as possible toxic agents, seeing that both of these molecules have a well-recognised origin in muscular tissue in the form of inosinic acid.

The part, if any, which may be played in the initiation of this syndrome by lowered blood-pressure consequent on shock has yet to be determined. Bywaters and Beall, while recognising that oliguria may be contributed to by a fall of systemic pressure and also by dehydration, could not attribute primary significance to either of these factors in their cases. There appears also to be general agreement that the degree and kind of renal functional disturbance which develops after crushing of the limbs is quite distinct from any of the sequelæ of ordinary surgical shock, and the exact pathology of the renal lesion itself is required in order to throw some light on this special feature. Maitland (1941) has suggested that the renal failure may be caused by vascular stasis in the kidneys resulting from low blood-pressure and aggravated by hæmoconcentration, while the circulation is flooded by abnormal protein from damaged muscles. It would be impossible at present to deny significance to any of these factors acting separately, but it does not seem a good argument that they would act concurrently in the early hours when injury appears to be inflicted on the kidneys; an accumulation of abnormal products in the blood would imply a fair circulation even through the injured limb, and an important lesion confined to the kidneys would suggest that they had received an adequate dose of the toxic agent from blood which passed through them. The significance of selective involvement of the kidneys in the present cases can hardly be overlooked, and it may be set in contrast to the lack of evidence for damage of other organs—the liver, for example, appears to function normally, for urea formation proceeds unchecked and large amounts accumulate in the blood. In considering possible reasons for specific localisation of damage in the kidneys attention may be drawn to a fundamental observation in experimental nephritis—that renal tubular damage can be most surely produced when the renal blood-flow is normally abundant and the concentrating power of the organs is unimpaired; for these reasons they sustain a more intensive attack by the toxic agents than do other tissues.

SUMMARY

The most definite changes found in the kidneys from two cases of crush syndrome are restricted to the ascending limbs of Henle's loop and second convoluted tubules; the lesions are in a healing stage.

The most severe of the tubular lesions implicate the walls of small venules, into which many of them have perforated.

The special localisation of these lesions may depend on change of reaction in the tubular contents at these levels.

Uric acid and phosphoric acid are substances capable of producing selective damage in these tubular segments.

We are indebted to Mr. Arthur Gray for permission to abstract the clinical notes of the cases and to Dr. Robert Cruickshank for his assistance in procuring the pathological materials. Reproductions of photographs by Mr. John Kirkpatrick.

T.N.T. JAUNDICE

ROBERT M. EVANS, M.B. CAMB.
MEDICAL REGISTRAR AT THE ROYAL SOUTHERN HOSPITAL, LIVERPOOL

THIS is an account of observations on seven patients employed in an ordnance filling factory and suffering from toxic jaundice, apparently caused by trinitrotoluene. The condition is not uncommon under the present war conditions, and early diagnosis and treatment are essential. All our cases have occurred within 6 months of beginning employment at the ordnance factory, and in one fatal case the patient had been in contact with explosives for only 3 weeks when symptoms appeared. Six out of seven cases were in women, three of whom were unmarried; there was no history of pregnancy toxæmia in any patient. Two of the patients died.

SYMPTOMATOLOGY

Nausea or vomiting was the first symptom noticed in five patients; in the remaining two jaundice and cyanosis were the first symptoms. After an interval lasting up to 12 days jaundice was noticed. A constant early symptom was vague epigastric pain or discomfort and anorexia which preceded the appearance of jaundice by several days.

Jaundice appeared in all the patients within 12 days of the onset of symptoms. The colour in the early stages was the lemon yellow of toxic jaundice, to be distinguished from the more greenish yellow of obstructive jaundice. This colour is like that of a one in a thousand aqueous solution of acriflavine, and is really lemon yellow with a trace of orange. It is readily distinguished by clinical students from the colour of obstructive jaundice patients, but may be confused with that of catarrhal jaundice. Difficulty may arise because many of the healthy workers show some orange tinting of the hair and exposed skin from the local action of the explosives. In three of the patients the jaundice increased after admission and became rather darker. A tendency to bruising was noticeable in all the patients whose jaundice was well marked, and petechial hæmorrhages were a prominent feature of both the fatal cases. Cyanosis and anæmia were only observed in two of the patients, and it must be noted that cyanosis is very common in these workers and is not necessarily related in any way to jaundice. The liver was not grossly enlarged in any case, and was only palpable in one patient who subsequently developed signs of cirrhosis.

The temperature remained subnormal except in the terminal phase of the two fatal cases. There were no rigors and no patient complained of chills. The pulse-rate was variable, but was usually about 80 per min in most patients. The absence of fever and rigors is one of the main differential points between this condition and catarrhal jaundice.

The urine contained bile-pigments in all cases, and there was albuminuria at some period in four patients. Webster's test[1] demonstrated the excretion of trinitrotoluene in the urine, but was not constantly positive in all patients, only becoming so during treatment in some cases. Many of the workers in trinitrotoluene give a positive Webster test; this indicates not intoxication but only excretion of the substance. Leucine and tyrosine crystals were not demonstrated in the urine of any patients.

The blood in all cases gave a positive direct and indirect van den Bergh reaction. No constant changes could be demonstrated spectroscopically, because owing to enemy action adequate facilities were not available. Anæmia was only severe in one patient who developed aplastic anæmia after the jaundice had resolved. The white-cell count showed a leucocytosis of up to 15,000, with relative polymorphonuclear increase in several patients (this has been observed in some apparently normal workers).

The lævulose-tolerance test was performed as a routine during convalescence, but showed no abnormality in any of the cases which reached this stage.

No evidence of the presence or formation of gall-stones was found at any stage.

AUTOPSY FINDINGS

Two patients have died, one from acute liver atrophy 16 days after the appearance of jaundice, the other from aplastic anæmia 18 weeks after the onset of jaundice and 9 weeks after its disappearance.

The findings in the first case were those of acute yellow atrophy of the liver. There was extensive jaundice, with many ecchymoses and petechial hæmorrhages on all serous membranes. The liver was grossly shrunken, soft and bile-stained, and weighed only 21 oz.; the appearances were those of the necrotic stage of acute yellow atrophy. The spleen showed some softening but was otherwise normal. The bone marrow was red in the whole length of the right femur. The kidneys showed poor differentiation of medulla from cortex (possibly partly post mortem change). Other organs showed no gross abnormality apart from bile-staining. Sections showed gross necrosis and disorganisation of the liver lobules, with some infiltration with round cells, and much amorphous debris, presumably from broken-down liver cells. The bile-ducts were not much affected, and did not show any inflammatory or hyperplastic changes.

The second fatal case was of special interest, for the jaundice had resolved completely 9 weeks before the patient died of aplastic anæmia, of which there was no sign while the jaundice was present. The post-mortem appearances were as follows: Pallor of the skin and some ecchymoses. The fauces and soft palate were ulcerated. The liver was finely granular and somewhat shrunken. The cut surface of the liver showed some pale areas of degenerating liver tissue, and pink areas of developing fibrosis. It weighed 40 oz. The spleen and kidneys showed no gross abnormality. The marrow of two ribs, the sternum, lumbar vertebræ and upper halves of both femurs was reddish, but not as red as typical hyperplastic marrow. Other organs showed no gross abnormality. Sections showed subacute necrosis of the liver, with some fatty degeneration, hypertrophy and fibrosis. Marrow smears showed no evidence of myelocytes or nucleated red cells.

CLINICAL COURSE AND TREATMENT

The patients must be removed from contact with trinitrotoluene as soon as the condition is suspected, and put at rest. On admission to hospital all the patients except one were given 20 g. of glucose daily in drinks and 15 units of insulin per day; in this one case the jaundice persisted for 2 months—about a fortnight longer than the average period for the others. Vitamin C, 100 mg., was given daily by mouth. A light diet was given and symptomatic treatment ordered as required. It should be remembered that many drugs—e.g., sulphonamides, chloral hydrate and amidopyrine—may cause damage to the liver or bone-marrow, and so are to be avoided in T N T poisoning. The jaundice in several cases increased after admission to hospital, but began to fade after 1–2 weeks, and in four cases was gone within 6 weeks; one other resolved after 8 weeks, and a second resolved slowly about 3 months after the onset.

The true end-results of the condition in these patients cannot yet be estimated, for it is only 6 months since the first patient became jaundiced. The present condition of all the patients may be summarised thus:

One patient has died of acute yellow atrophy (case 1).

One patient developed agranulocytic angina with the blood-picture of aplastic anæmia, and in spite of all treatment died 14 days after readmission (case 2).

One patient has ascites, apparently from cirrhosis, but is now free from jaundice, and the effusion has to be tapped only at increasing intervals (case 3).

Four patients have apparently recovered and are free from all symptoms.

The final result of the four apparent recoveries and the patient with cirrhosis can only be judged when further time has elasped and liver-function tests have been carried out. The findings in the liver of the second fatal case seem to indicate that a good deal of regeneration of liver tissue can take place, and probably has taken place in the apparent recoveries.

CASE-RECORDS

CASE 1.—Unmarried woman, aged 21, started work at ordnance factory in March, 1941. On July 9 she was admitted to hospital complaining of jaundice, noticed for about 4 weeks; on July 5 she had felt pain in the epigastrium, and had vomited next day. The bowels were regular, but pale stools were noticed about July 5. On admission there was a fairly well-marked yellow jaundice, with clean moist tongue and normal temperature and pulse-rate; the urine contained bile-pigments, but no other abnormal constituent. Van den Bergh reaction, positive direct and indirect. Webster test on the urine became positive on July 14 and a faint trace of albumin appeared in the urine on July 17. The blood picture was normal. On the 19th the jaundice was deeper, and the patient was rather dazed, with poor pulse and persistent vomiting. Intravenous glucose saline drip was instituted, but her condition deteriorated. On the 21st petechiæ and ecchymoses appeared, and the liver dullness was decreased. The patient died on July 23 with high terminal pyrexia.

CASE 2.—Unmarried woman, aged 35, started work with T N T on March 10. On the 31st she noticed nausea, succeeded a day or two later by vomiting; epigastric discomfort and jaundice appeared on April 6. She was admitted to hospital on April 12. There was well marked jaundice, with bile pigments in the urine and pale stools. Constipation was not noted. The temperature and pulse were normal, and no other abnormalities were found. At this time blood examination revealed 5% reticulocytes and no anæmia. The jaundice became extremely deep about May 5 and then faded. A trace of albumin was found in the urine at this time. On June 7 the patient was symptom-free, with no jaundice and a normal lævulose-tolerance test. She was discharged from hospital and went away on holiday.

On Aug. 2 she returned from holiday and was readmitted complaining of sore throat and petechial rash. Blood examination revealed agranulocytosis and aplastic anæmia, which were the cause of her ulcerated throat. The temperature fluctuated about 101° F. and the pulse rate about 110 per min. Daily transfusions of fresh blood, with intramuscular liver extract and pentnucleotide daily failed to influence the condition, and she died on Aug. 16. During this second period in hospital there was no jaundice.

CASE 3.—Married woman, aged 42, with history of three normal pregnancies. Started work at factory on Feb. 7, 1941. On April 20 she vomited and noticed dark urine; next day she noticed a tinge of jaundice and felt vague epigastric pain. She was admitted to hospital on April 25 with mild jaundice. The temperature and pulse rate were subnormal and remained so. The liver was not palpable, but there was slight tenderness on pressure in the right subcostal region. The urine contained a trace of bile pigments and the blood van den Bergh test was positive both direct and indirect. No other abnormality was detected. The jaundice persisted and the patient vomited once after admission. On

lesion is again almost restricted to the lower nephron segments, and he agrees with Dunn and Polson in attributing the special localisation of lesions at this level to change of reaction in the filtrate, added no doubt to increase of concentration which has been effected at higher levels.

A feature which appears to be unique among the tubular changes in the present cases is the localisation of the most intense damage at points where the lower nephron segments lie in close proximity to veins. Further confirmation of this occurrence in other cases would be desirable but in our material the frequency of the association is so remarkable as to suggest a definite causal nexus. In uric-acid nephritis there seems to be little doubt that the lesion is determined by precipitation of the agent from a soluble form in which it is relatively harmless to a solid which exerts the destructive effect. It seems possible that in the present cases also a substance of special toxicity is produced in the presence of acid, and that the proximity of venous blood has an influence in permitting a greater swing towards an acid reaction in this area than is reached at other parts.

Nothing certain is known as yet of the nature or source of any toxic agent which may be responsible for the renal damage in cases of crush syndrome. The available facts, however, appear to justify the primary view to which most observers have adhered—that after release of the affected tissue from a compressed and more or less ischæmic state something toxic is absorbed from it into the circulation as the vessels reopen, and that the toxic agent affects the kidney in the course of excretion. The number and kinds of possible toxic agents which could so arise is conjectural and the suggestion that the cast material, which apparently contains myohæmoglobin (Bywaters and Delory 1941), is toxic is not to be ignored. Some light will probably be thrown on the genesis of this condition by experimentation with products obtained from muscle or other tissues. While not attempting to prejudge the results of this investigation, we suggest that both uric acid and phosphoric acid may well come under review as possible toxic agents, seeing that both of these molecules have a well-recognised origin in muscular tissue in the form of inosinic acid.

The part, if any, which may be played in the initiation of this syndrome by lowered blood-pressure consequent on shock has yet to be determined. Bywaters and Beall, while recognising that oliguria may be contributed to by a fall of systemic pressure and also by dehydration, could not attribute primary significance to either of these factors in their cases. There appears also to be general agreement that the degree and kind of renal functional disturbance which develops after crushing of the limbs is quite distinct from any of the sequelæ of ordinary surgical shock, and the exact pathology of the renal lesion itself is required in order to throw some light on this special feature. Maitland (1941) has suggested that the renal failure may be caused by vascular stasis in the kidneys resulting from low blood-pressure and aggravated by hæmoconcentration, while the circulation is flooded by abnormal protein from damaged muscles. It would be impossible at present to deny significance to any of these factors acting separately, but it does not seem a good argument that they would act concurrently in the early hours when injury appears to be inflicted on the kidneys; an accumulation of abnormal products in the blood would imply a fair circulation even through the injured limb, and an important lesion confined to the kidneys would suggest that they had received an adequate dose of the toxic agent from blood which passed through them. The significance of selective involvement of the kidneys in the present cases can hardly be overlooked, and it may be set in contrast to the lack of evidence for damage of other organs—the liver for example, appears to function normally, for urea formation proceeds unchecked and large amounts accumulate in the blood. In considering possible reasons for specific localisation of damage in the kidneys attention may be drawn to a fundamental observation in experimental nephritis—that renal tubular damage can be most surely produced when the renal blood-flow is normally abundant and the concentrating power of the organs is unimpaired; for these reasons they sustain a more intensive attack by the toxic agents than do other tissues.

SUMMARY

The most definite changes found in the kidneys from two cases of crush syndrome are restricted to the ascending limbs of Henle's loop and second convoluted tubules; the lesions are in a healing stage.

The most severe of the tubular lesions implicate the walls of small venules, into which many of them have perforated.

The special localisation of these lesions may depend on change of reaction in the tubular contents at these level.

Uric acid and phosphoric acid are substances capable of producing selective damage in these tubular segments.

We are indebted to Mr Arthur Gray for permission to abstract the clinical notes of the cases and to Dr Robert Cruickshank for his assistance in procuring the pathological materials. Reproductions of photographs by Mr John Kirkpatrick.

T.N.T. JAUNDICE

ROBERT M. EVANS, M.B. CAMB.
MEDICAL REGISTRAR AT THE ROYAL SOUTHERN HOSPITAL, LIVERPOOL

THIS is an account of observations on seven patients employed in an ordnance filling factory and suffering from toxic jaundice, apparently caused by trinitrotoluene. The condition is not uncommon under the present war conditions, and early diagnosis and treatment are essential. All our cases have occurred within 6 months of beginning employment at the ordnance factory, and in one fatal case the patient had been in contact with explosives for only 3 weeks when symptoms appeared. Six out of seven cases were in women, three of whom were unmarried; there was no history of pregnancy toxæmia in any patient. Two of the patients died.

SYMPTOMATOLOGY

Nausea or vomiting was the first symptom noticed in five patients; in the remaining two jaundice and cyanosis were the first symptoms. After an interval lasting up to 12 days jaundice was noticed. A constant early symptom was vague epigastric pain or discomfort and anorexia which preceded the appearance of jaundice by several days.

Jaundice appeared in all the patients within 12 days of the onset of symptoms. The colour in the early stages was the lemon yellow of toxic jaundice, to be distinguished from the more greenish yellow of obstructive jaundice. This colour is like that of a one in a thousand aqueous solution of acriflavine, and is really lemon yellow with a trace of orange; it is readily distinguished by clinical students from the colour of obstructive jaundice patients, but may be confused with that of catarrhal jaundice. Difficulty may arise because many of the healthy workers show some orange tinting of the hair and exposed skin from the local action of the explosives. In three of the patients the jaundice increased after admission and became rather darker. A tendency to bruising was noticeable in all the patients whose jaundice was well marked, and petechial hæmorrhages were a prominent feature of both the fatal cases. Cyanosis and anæmia were only observed in two of the patients, and it must be noted that cyanosis is very common in these workers and is not necessarily related in any way to jaundice. The liver was not grossly enlarged in any case, and was only palpable in one patient who subsequently developed signs of cirrhosis.

very deep according to the amount of T N T present and appears quickly and just as quickly fades If no T N T be present a light brown colour only results and persists

With this simplified technique the test is sensitive to 1 part in 10,000 It does not exclude anthraquinone derivatives (from the purgatives mentioned), which give a similar but pinker colour which persists

---

TRIGEMINAL NEURALGIA

A SUGGESTED BASIS OF TREATMENT

W E ADAMS,
M B, M SC N Z
LECTURER IN ANATOMY, UNIVERSITY OF LEEDS

WILLIAM ROBINSON,
M.B LEEDS
SENIOR HOUSE PHYSICIAN, GENERAL INFIRMARY, LEEDS

THE view, which many have held, that the paroxysms of trigeminal neuralgia are ischæmic in origin has never received convincing support Even Leriche (1939), who favours this view, admits that the treatment of trigeminal neuralgia by sympathectomy, with the object of producing a vasodilatation of the trigeminal vessels, offers little hope of success Nevertheless there is increasing evidence, both physiological and pathological, that the normal functioning of peripheral nerves is dependent upon the integrity of their blood-supply Koch (1926) has shown that ischæmia of mammalian nerve produces significant physiological changes in the nerve, and that when the ischæmia disappears the nerve returns again to normal Should the ischæmia persist, as in pathological occlusion of the vasa nervorum, more permanent effects result (Woltman and Wilder 1929, Randall 1938, and others)

Unfortunately, little is known concerning the detailed vascular supply of peripheral nerves In the trigeminal, however, the Gasserian ganglion has been shown to be very vascular (Stöhr 1928) and to receive its supply from the internal carotid artery, while the remainder of the nerve resembles nerves elsewhere in receiving a regional blood-supply (Grigorowsky 1928) Since physiological and pathological evidence suggests that the blood-supply of any nerve is not only adequate but also essential for its normal requirements, it seems to us that ischæmia of a nerve, whether angiospastic or otherwise should be considered as a possible factor in peripheral nervous lesions where no other obvious cause presents itself In the case of trigeminal neuralgia this hypothesis deserves the fullest investigation, and should not be rejected merely because of the failure of cervical sympathectomy

The success which has recently been obtained in angiospastic conditions such as Menière's disease (Atkinson 1941) and even in one case of trigeminal neuralgia (Cooper 1938), by exhibiting vasodilator drugs over long periods encouraged us to explore the possibilities of this form of treatment in trigeminal neuralgia In the first cases which were available we tried to induce the paroxysmal pain by administering the vasoconstrictor drugs, adrenaline and benzedrine, believing that its production in this way would suggest an angiospastic basis Abolition, then, of both the induced and spontaneous pains would afford not only circumstantial support for our theory but also a new means of alleviating the pain in those cases which show such vasomotor responses Because it has been found in Menière's disease and nerve deafness to be the most effective vasodilator, we relied mainly on nicotinic acid, and not on acetylcholine which was used by Cooper in trigeminal neuralgia In cases 1–7 treatment with nicotinic acid was begun at once in an attempt to stabilise the dosage It was found, however, that there is considerable individual variation in the response to this drug, and, unless relief was obtained earlier, it was at times necessary to increase the dosage until signs of generalised vasodilatation appeared

CASE RECORDS

CASE 1 —A woman aged 52, with 2½ years' history of supraorbital pain of typical paroxysmal type, accompanied by a facial tic Thorough examination revealed no cause for the symptoms Blood pressure 135/95 mm Hg

During an intermission of the symptoms a preliminary injection of 0 7 c cm of 1 in 1000 adrenaline induced, almost immediately, supraorbital pain—resembling in every respect the usual spontaneous pain—with tenderness over the supraorbital notch During a subsequent spontaneous paroxysm 50 mg nicotinic acid was given by mouth with no apparent effect After 40 minutes a further 50 mg was administered; this resulted in some diminution of the pain after 20 minutes, but did not abolish it A capsule of amyl nitrite was then given This produced striking, almost instantaneous relief—the pain disappeared completely, to the delight of the patient who was able to sleep without a sedative for the first time in many weeks Although she was convinced of the efficacy of amyl nitrite, it was nevertheless probable that it merely augmented the effect of the previous subliminal doses of nicotinic acid Treatment by nicotinic acid, 50 mg t d.s, was then continued, and during the 10 days that the patient was under our observation there was no recurrence of the pain. Injections of adrenaline during this period were ineffective. As in Cooper's case, the facial tic was not influenced by the treatment

CASE 2 —A woman, aged 68, with 2½ years' history of trigeminal neuralgia involving the second division of the nerve Blood-pressure 150/105 mm Hg

At first the patient was given benzedrine sulphate, 5 mg. b d The paroxysms became considerably more frequent, and she complained bitterly of their increasing severity On two occasions a capsule of amyl nitrite relieved the paroxysms. The benzedrine was then stopped and nicotinic acid given, 50 mg b d Over a number of days this treatment reduced the paroxysms in frequency (from 15–20 a day to 3 or 4) and in severity

CASE 3 —A man, aged 48, with 5 years' history of trigeminal neuralgia involving the second division of the nerve After a remission of 2 years the pain had returned with its original severity It appeared 5 or 6 times a day and lasted 1–3 hours Blood pressure 130/90 mm Hg

Treatment with nicotinic acid, 50 mg b d, was started at once and had a definite effect Apart from one paroxysm shortly after the treatment began, the patient had complete freedom from pain for 4 days During this time attempts were made to induce the pain by injection of adrenaline but without effect After 4 days the nicotinic acid was stopped and he was put on benzedrine sulphate 5 mg t d s Attacks of pain recommenced and increased gradually in frequency and severity as the benzedrine was continued Attempts to relieve the paroxysm during this time by giving acetylcholine were without success, probably because it was unable to counteract the constrictor effect of the benzedrine

CASE 4 —A woman, aged 49, with 1 year's history of paroxysmal neuralgia of the second division of the trigeminal nerve Blood pressure 138/90 mm Hg

Treatment with nicotinic acid, 50 mg b d, was begun on July 14, 1941 This was without effect The dose was then increased to 50 mg q d, which produced considerable relief, further improvement resulted on again increasing the dose to 75 mg t d The dosage has subsequently varied between 75 mg t d and 75 mg q d according to the subjective responses This resulted in progressive improvement leading to almost complete relief by the end of the second month of treatment This has since been maintained, and treatment is still continuing

CASE 5 —A woman, aged 62, with neuralgia of the first and second divisions of the trigeminal nerve over a period of several years The pain was typically paroxysmal with short intermissions of almost complete relief Blood pressure 140/85 mm Hg

Treatment with nicotinic acid, 50 mg b d, began on June 19, 1941 At the end of a month the paroxysms had lessened in frequency and severity An increase during the second month to 50 mg t d resulted in further improvement, the patient sleeping better than she had for several months A further increase to 50 mg q d has resulted in almost complete relief except for very occasional "stabs" of pain. Treatment is continuing

CASE 6 —A woman, aged 39, who had been a nurse, with trigeminal neuralgia involving the second and third divisions Unerupted wisdom teeth had been removed with no effect Paroxysms occurred every 2–3 weeks and lasted from 1–2 hours to 10 days Blood pressure 130/80 mm Hg

She was first seen on Sept 3, 1941 during the onset of a paroxysm, which responded dramatically to inhalation of amyl nitrite, disappearing in a little over a minute She was then placed on nicotinic acid, 50 mg q d, in just over 3 weeks this has considerably reduced the severity but not the frequency of the paroxysms Treatment is continuing

May 3 the liver edge was palpable She was given glucose and insulin, and a light low fat diet On May 14 the jaundice was deeper and the liver no longer palpable On June 3 there were œdema of ankles and signs of ascites, and the patient was seriously ill Paracentesis on the 4th yielded 10 pints of yellow fluid, on the 7th 21 pints of fluid was obtained Six further paracenteses were performed between June 18 and Aug 4, during which period the jaundice gradually subsided and the general condition improved On Aug 5 she began to pass more urine, and further paracentesis has been unnecessary On Sept 1 she was improving steadily, with no abdominal distension and no jaundice of the conjunctivæ, although skin pigmentation remained

DISCUSSION

It seems that some people are much more susceptible to trinitrotoluene than others It also seems probable that if workers do not develop some toxic manifestation in their first 6 months they will by then have acquired some immunity, if they are not naturally unsusceptible

Moore [2] showed that the main channel of absorption is by the skin, and it is noteworthy that while dermatitis is common among workers at the factory not one of the patients in this series had been troubled by any skin eruption Apparently there is a susceptibility or sensitivity of different tissues in different individuals

The patient who died of acute liver necrosis had apparently a hyperplastic marrow, and yet the blood-picture showed only a very slight anæmia and no increase in reticulocytes, in the other fatal case, where the liver was apparently able to carry out most functions adequately, there was an aplastic blood-picture, but the marrow was not aplastic Is it possible that the aplastic anæmia which rarely follows trinitrotoluene jaundice is due to inability of a damaged liver to supply some factor essential for hæmopoiesis? In any case, there seems to be justification for treatment with liver extracts during the jaundice The best line of treatment of the developed condition is not easy to lay down, but the importance of prophylaxis is well recognised [3] At the filling factory the precautions include protective overalls and gloves for workers, with supervision of washing of hands, arms, face, and neck after work, ventilation is augmented by a system of vacuum pipes with openings near every worker to remove dust and fumes, proper meals are provided in a canteen, and workers are encouraged to take outdoor exercise and a healthy diet Work in actual contact with T N T is alternated with other work, and weekly medical inspection is carried out to detect any signs of intoxication Unfortunately patients may report sick to their home doctor without notifying the factory medical officer, and if they do not mention that they have worked with trinitrotoluene catarrhal jaundice or other lesion may be wrongly suspected and treatment delayed The earliest possible diagnosis and removal of patients from contact seem to be essential if the present considerable mortality and morbidity are to be reduced

SUMMARY

Seven cases of T N T jaundice occurred in workers in an ordnance filling factory, of whom two have died

The jaundice appeared within 6 months of beginning work at the factory, and was a typical orange yellow

The associated symptoms were nausea, anorexia and epigastric discomfort, liver enlargement and pyrexia were absent, distinguishing the condition from catarrhal jaundice, with which it is likely to be confused

Autopsy on the fatal cases revealed acute yellow atrophy of the liver and hyperplasia of the bone-marrow in one patient, and subacute liver necrosis and a hyperplastic bone-marrow in the other, whose death was due to aplastic anæmia

Treatment was by glucose, insulin and vitamin C

Prophylaxis is important, the main measures being protection of the skin, washing, adequate ventilation of factories, and a healthy life and full diet for workers

I wish to thank my colleagues and the senior medical staff of the hospital for their help and encouragement

IMPROVED WEBSTER TEST FOR T.N.T. DERIVATIVE IN URINE

JOHN INGHAM, F I C
BIOCHEMIST TO THE MEDICAL UNIT, SCHOOL OF MEDICINE, CARDIFF

THE test for trinitrotoluene (T N T) derivative in the urine is that introduced by Webster [1] and later improved both by him [2] and by Tutin [3] By a simple modification the sensitivity of the test may be enhanced and a positive result more frequently obtained This modification consists simply in boiling the mixture of urine and sulphuric acid before adding the ether, thereby ensuring a more thorough extraction of the T N T product from the urine The test is further improved, and the chances of detection increased still more, by using four times the quantity of urine recommended by Webster Here is the improved test in detail

Place 50 c cm of urine in a convenient sized beaker (400 c cm) and add 50 c cm of 20% (by volume) sulphuric acid (1 part conc H_2SO_4 + 4 parts H_2O) Mix

Place beaker on tripod, supported by wire gauze, and heat over bunsen flame till the liquid boils

Boil for one minute, allow to cool Cooling may be hastened by running cold water over outside of beaker

After cooling pour the mixture of urine and acid into a separatory funnel of 200 c cm capacity and add 50 c cm of ordinary (methylated) ether Shake up well and then allow to settle for about 15 minutes The lower layer of urine and sulphuric acid is next run off by removing the top stopper and opening the lower tap

The ethereal solution of acidified urine remaining in the separatory funnel is then washed twice with 1% aqueous solution of sodium carbonate This is done as follows Add 20–25 c cm 1% aqueous sodium carbonate, shake up, and after allowing to settle for 5–10 min run off the lower layer Repeat (*If the person has been taking purgatives* such as rhubarb, senna, cascara, phenolphthalein—which yield anthraquinone derivatives—the sodium carbonate solution will show a reddish violet colour)

After this treatment with sodium carbonate the ethereal solution in the funnel is washed with water, as follows Add 50 c cm tap water, shake up, allow to settle for 15 min, then run off the lower layer as before (Occasionally a troublesome emulsion forms in the ethereal extract while washing with water but it is easily dispersed by adding a few drops of absolute alcohol and shaking gently)

Now place 5 c cm of the ethereal extract, so washed and prepared, in a test tube and quickly add, without shaking, 5 c cm of a 5% alcoholic solution of potassium hydroxide (5 g caustic potash dissolved in 100 c cm of methylated spirit or absolute alcohol) A violet cloud indicates a positive result The liquid in the test tube should be watched carefully, *for the colour develops quickly* and just as quickly fades The intensity of the colour varies from the faintest tint to a deep violet according to the amount of T N T in the urine

The unused ethereal extract remaining in the separatory funnel need not be thrown away but may be collected and later separated off from any T N T by distillation It may then be used again in other tests

For the routine everyday urine examination of workers in T N T factories the technique may be simplified as follows

Apparatus required Two ordinary test tubes (7 in × ¾ in), Bunsen burner or spirit lamp

Reagents required 20% (by volume) sulphuric acid, ordinary (methylated) ether, 5% alcoholic solution of potassium hydroxide (freshly prepared)

Place about 10 c cm of urine into one test tube, add about an equal quantity of the 20% sulphuric acid, shake and bring to the boil, cool thoroughly under the water tap

When cold add about 10 c cm of the ether and shake well, allow to stand a few minutes till ether floats to the top Pour some of the supernatant ether into the other test tube and to it add about 2 c cm of the 5% alcoholic potassium hydroxide solution A dirty reddish purple colour develops *at once* if T N T is present The tint varies from faint to very deep according to the amount of T.N.T. present and appears quickly and just as quickly fades. If no T.N.T. be present a light brown colour only results and persists.

---

[1] Webster, T A *Lancet*, 1916, 2, 1029

[2] Webster, *Spec Rep Ser med Res Coun Lond* No 53, 1921

[3] Tutin, F *Lancet*, 1918, 2, 554

With this simplified technique the test is sensitive to 1 part in 10,000. It does not exclude anthraquinone derivatives (from the purgatives mentioned), which give a similar but pinker colour which persists.

TRIGEMINAL NEURALGIA

A SUGGESTED BASIS OF TREATMENT

W. E. ADAMS,
M.B., M.SC. N.Z.
LECTURER IN ANATOMY,
UNIVERSITY OF LEEDS

WILLIAM ROBINSON,
M.B. LEEDS
SENIOR HOUSE PHYSICIAN, GENERAL
INFIRMARY, LEEDS

THE view, which many have held, that the paroxysms of trigeminal neuralgia are ischæmic in origin has never received convincing support. Even Leriche (1939), who favours this view, admits that the treatment of trigeminal neuralgia by sympathectomy with the object of producing a vasodilatation of the trigeminal vessels, offers little hope of success. Nevertheless there is increasing evidence, both physiological and pathological, that the normal functioning of peripheral nerves is dependent upon the integrity of their blood-supply. Koch (1926) has shown that ischæmia of mammalian nerve produces significant physiological changes in the nerve, and that when the ischæmia disappears the nerve returns again to normal. Should the ischæmia persist, as in pathological occlusion of the vasa nervorum, more permanent effects result (Woltman and Wilder 1929, Randall 1938, and others).

Unfortunately, little is known concerning the detailed vascular supply of peripheral nerves. In the trigeminal, however, the Gasserian ganglion has been shown to be very vascular (Stöhr 1928) and to receive its supply from the internal carotid artery, while the remainder of the nerve resembles nerves elsewhere in receiving a regional blood-supply (Grigorovsky 1928). Since physiological and pathological evidence suggests that the blood-supply of any nerve is not only adequate but also essential for its normal requirements, it seems to us that ischæmia of a nerve, whether angiospastic or otherwise, should be considered as a possible factor in peripheral nervous lesions where no other obvious cause presents itself. In the case of trigeminal neuralgia this hypothesis deserves the fullest investigation, and should not be rejected merely because of the failure of cervical sympathectomy.

The success which has recently been obtained in angiospastic conditions such as Menière's disease (Atkinson 1941) and even in one case of trigeminal neuralgia (Cooper 1938) by exhibiting vasodilator drugs over long periods encouraged us to explore the possibilities of this form of treatment in trigeminal neuralgia. In the first cases which were available we tried to induce the paroxysmal pain by administering the vasoconstrictor drugs, adrenaline and benzedrine, believing that its production in this way would suggest an angiospastic basis. Abolition, then, of both the induced and spontaneous pains would afford not only circumstantial support for our theory but also a new means of alleviating the pain in those cases which show such vasomotor responses. Because it has been found in Menière's disease and nerve deafness to be the most effective vasodilator, we relied mainly on nicotinic acid, and not on acetylcholine which was used by Cooper in trigeminal neuralgia. In cases 4–7 treatment with nicotinic acid was begun at once in an attempt to stabilise the dosage. It was found, however, that there is considerable individual variation in the response to this drug, and, unless relief was obtained earlier, it was at times necessary to increase the dosage until signs of generalised vasodilatation appeared.

CASE-RECORDS

CASE 1.—A woman, aged 52, with 2½ years' history of supraorbital pain of typical paroxysmal type, accompanied by a facial tic. Thorough examination revealed no cause for the symptoms. Blood-pressure 135/95 mm. Hg.

During an intermission of the symptoms a preliminary injection of 0·7 c.cm. of 1 in 1000 adrenaline induced, almost immediately, supraorbital pain—resembling in every respect the usual spontaneous pain—with tenderness over the supraorbital notch. During a subsequent spontaneous paroxysm 50 mg. nicotinic acid was given by mouth with no apparent effect. After 40 minutes a further 50 mg. was administered; this resulted in some diminution of the pain after 20 minutes, but did not abolish it. A capsule of amyl nitrite was then given. This produced striking, almost instantaneous relief—the pain disappeared completely, to the delight of the patient who was able to sleep without a sedative for the first time in many weeks. Although she was convinced of the efficacy of amyl nitrite, it was nevertheless probable that it merely augmented the effect of the previous subminimal doses of nicotinic acid. Treatment by nicotinic acid, 50 mg. t.d.s., was then continued, and during the 10 days that the patient was under our observation there was no recurrence of the pain. Injections of adrenaline during this period were ineffective. As in Cooper's case, the facial tic was not influenced by the treatment.

CASE 2.—A woman, aged 68, with 2½ years' history of trigeminal neuralgia involving the second division of the nerve. Blood-pressure 150/105 mm. Hg.

At first the patient was given benzedrine sulphate, 5 mg. b.d. The paroxysms became considerably more frequent, and she complained bitterly of their increasing severity. On two occasions a capsule of amyl nitrite relieved the paroxysms. The benzedrine was then stopped and nicotinic acid given, 50 mg. b.d. Over a number of days this treatment reduced the paroxysms in frequency (from 15–20 a day to 3 or 4) and in severity.

CASE 3.—A man, aged 48, with 5 years' history of trigeminal neuralgia involving the second division of the nerve. After a remission of 2 years the pain had returned with its original severity. It appeared 5 or 6 times a day and lasted 1–3 hours. Blood-pressure 130/90 mm. Hg.

Treatment with nicotinic acid, 50 mg. b.d., was started at once and had a definite effect. Apart from one paroxysm shortly after the treatment began, the patient had complete freedom from pain for 4 days. During this time attempts were made to induce the pain by injection of adrenaline but without effect. After 4 days the nicotinic acid was stopped and he was put on benzedrine sulphate 5 mg. t.d.s. Attacks of pain recommenced and increased gradually in frequency and severity as the benzedrine was continued. Attempts to relieve the paroxysm during this time by giving acetylcholine were without success, probably because it was unable to counteract the continuous effect of the benzedrine.

CASE 4.—A woman, aged 49, with 1 year's history of paroxysmal neuralgia of the second division of the trigeminal nerve. Blood-pressure 138/90 mm. Hg.

Treatment with nicotinic acid, 50 mg. b.d., was begun on July 14, 1941. This was without effect. The dose was then increased to 50 mg. q.d., which produced considerable relief; further improvement resulted on again increasing the dose to 75 mg. t.d. The dosage has subsequently varied between 75 mg. t.d. and 75 mg. q.d. according to the subjective responses. This resulted in progressive improvement leading to almost complete relief by the end of the second month of treatment. This has since been maintained, and treatment is still continuing.

CASE 5.—A woman, aged 62, with neuralgia of the first and second divisions of the trigeminal nerve over a period of several years. The pain was typically paroxysmal with short intermissions of almost complete relief. Blood-pressure 149/85 mm. Hg.

Treatment with nicotinic acid, 50 mg. b.d., begun on June 19, 1941. At the end of a month the paroxysms had lessened in frequency and severity. An increase during the second month to 50 mg. t.d. resulted in further improvement, the patient sleeping better than she had for several months. A further increase to 50 mg. q.d. has resulted in almost complete relief except for very occasional "stabs" of pain. Treatment is continuing.

CASE 6.—A woman, aged 39, who had been a nurse, with trigeminal neuralgia involving the second and third divisions. Unerupted wisdom teeth had been removed with no effect. Paroxysms occurred every 2–3 weeks and lasted from 1–2 hours to 10 days. Blood-pressure 130/80 mm. Hg.

She was first seen on Sept. 3, 1941, during the onset of a paroxysm, which responded dramatically to inhalation of amyl nitrite, disappearing in a little over a minute. She was then placed on nicotinic acid, 50 mg. q.d.; in just over 3 weeks this has considerably reduced the severity but not the frequency of the paroxysms. Treatment is continuing.

May 3 the liver edge was palpable She was given glucose and insulin, and a light low fat diet On May 14 the jaundice was deeper and the liver no longer palpable On June 3 there were œdema of ankles and signs of ascites, and the patient was seriously ill Paracentesis on the 4th yielded 10 pints of yellow fluid, on the 7th 21 pints of fluid was obtained Six further paracenteses were performed between June 18 and Aug 4, during which period the jaundice gradually subsided and the general condition improved On Aug 5 she began to pass more urine, and further paracentesis has been unnecessary On Sept 1 she was improving steadily, with no abdominal distension and no jaundice of the conjunctivæ, although skin pigmentation remained

DISCUSSION

It seems that some people are much more susceptible to trinitrotoluene than others It also seems probable that if workers do not develop some toxic manifestation in their first 6 months they will by then have acquired some immunity, if they are not naturally unsusceptible

Moore[2] showed that the main channel of absorption is by the skin, and it is noteworthy that while dermatitis is common among workers at the factory not one of the patients in this series had been troubled by any skin eruption Apparently there is a susceptibility or sensitivity of different tissues in different individuals

The patient who died of acute liver necrosis had apparently a hyperplastic marrow, and yet the blood-picture showed only a very slight anæmia and no increase in reticulocytes, in the other fatal case, where the liver was apparently able to carry out most functions adequately, there was an aplastic blood-picture, but the marrow was not aplastic Is it possible that the aplastic anæmia which rarely follows trinitrotoluene jaundice is due to inability of a damaged liver to supply some factor essential for hæmopoiesis? In any case, there seems to be justification for treatment with liver extracts during the jaundice The best line of treatment of the developed condition is not easy to lay down, but the importance of prophylaxis is well recognised[3] At the filling factory the precautions include protective overalls and gloves for workers, with supervision of washing of hands, arms, face, and neck after work, ventilation is augmented by a system of vacuum pipes with openings near every worker to remove dust and fumes, proper meals are provided in a canteen, and workers are encouraged to take outdoor exercise and a healthy diet Work in actual contact with T N T is alternated with other work, and weekly medical inspection is carried out to detect any signs of intoxication Unfortunately patients may report sick to their home doctor without notifying the factory medical officer, and if they do not mention that they have worked with trinitrotoluene catarrhal jaundice or other lesion may be wrongly suspected and treatment delayed The earliest possible diagnosis and removal of patients from contact seem to be essential if the present considerable mortality and morbidity are to be reduced

SUMMARY

Seven cases of T N T jaundice occurred in workers in an ordnance filling factory, of whom two have died

The jaundice appeared within 6 months of beginning work at the factory, and was a typical orange yellow

The associated symptoms were nausea, anorexia and epigastric discomfort, liver enlargement and pyrexia were absent, distinguishing the condition from catarrhal jaundice, with which it is likely to be confused

Autopsy on the fatal cases revealed acute yellow atrophy of the liver and hyperplasia of the bone-marrow in one patient, and subacute liver necrosis and a hyperplastic bone-marrow in the other, whose death was due to aplastic anæmia

Treatment was by glucose, insulin and vitamin C

Prophylaxis is important, the main measures being protection of the skin, washing, adequate ventilation of factories, and a healthy life and full diet for workers

I wish to thank my colleagues and the senior medical staff of the hospital for their help and encouragement

IMPROVED WEBSTER TEST FOR T.N.T. DERIVATIVE IN URINE

JOHN INGHAM, F I C
BIOCHEMIST TO THE MEDICAL UNIT, SCHOOL OF MEDICINE, CARDIFF

THE test for trinitrotoluene (T N T) derivative in the urine is that introduced by Webster[1] and later improved both by him[2] and by Tutin[3] By a simple modification the sensitivity of the test may be enhanced and a positive result more frequently obtained This modification consists simply in boiling the mixture of urine and sulphuric acid before adding the ether, thereby ensuring a more thorough extraction of the T N T product from the urine The test is further improved, and the chances of detection increased still more, by using four times the quantity of urine recommended by Webster Here is the improved test in detail

Place 50 c cm of urine in a convenient sized beaker (400 c cm) and add 50 c cm of 20% (by volume) sulphuric acid (1 part conc H_2SO_4 + 4 parts H_2O) Mix

Place beaker on tripod, supported by wire gauze, and heat over bunsen flame till the liquid boils

Boil for one minute, allow to cool Cooling may be hastened by running cold water over outside of beaker

After cooling pour the mixture of urine and acid into a separatory funnel of 200 c cm capacity and add 50 c cm of ordinary (methylated) ether Shake up well and then allow to settle for about 15 minutes The lower layer of urine and sulphuric acid is next run off by removing the *top stopper* and opening the lower tap

The ethereal solution of acidified urine remaining in the separatory funnel is then washed twice with 1% aqueous solution of sodium carbonate This is done as follows Add 20–25 c cm 1% aqueous sodium carbonate, shake up, and after allowing to settle for 5–10 min run off the lower layer Repeat (If the person has been taking purgatives such as rhubarb, senna, cascara, phenolphthalein—which yield anthraquinone derivatives—the sodium carbonate solution will show a reddish violet colour)

After this treatment with sodium carbonate the ethereal solution in the funnel is washed with water, as *follows* Add 50 c cm tap water, shake up, allow to settle for 15 min, *then* run off the lower layer as before (Occasionally a troublesome emulsion forms in the ethereal extract while washing with water but it is easily dispersed by adding a few drops of absolute alcohol and shaking gently)

Now place 5 c cm of the ethereal extract, so washed and prepared, in a test tube and quickly add, without shaking, 5 c cm of a 5% alcoholic solution of potassium hydroxide (5 g caustic potash dissolved in 100 c cm of methylated spirit or absolute alcohol) A violet cloud indicates a positive result The liquid in the test tube should be watched carefully, for the colour develops quickly and just as quickly fades The intensity of the colour varies from the faintest tint to a deep violet according to the amount of T N T in the urine

The unused ethereal extract remaining in the separatory funnel need not be thrown away but may be collected and later separated off from any T N T by distillation It may then be used again in other tests

For the routine everyday urine examination of workers in T N T factories the technique may be simplified as follows

Apparatus required Two ordinary test tubes (7 in × ¾ in), Bunsen burner or spirit lamp

Reagents required 20% (by volume) sulphuric acid, ordinary (methylated) ether, 5% alcoholic solution of potassium hydroxide (freshly prepared)

Place about 10 c cm of urine into one test tube, add about an equal quantity of the 20% sulphuric acid, shake and bring to the boil, cool thoroughly under the water tap

When cold add about 10 c cm of the ether and shake well, allow to stand a few minutes till ether floats to the top Pour some of the supernatant ether into the other test tube and to it add about 2 c cm of the 5% alcoholic potassium hydroxide solution A dirty reddish purple colour develops *at once* if T N T is present The tint varies from faint to

CONCENTRATED SERUM IN HEAD INJURIES

J W ALDREN TURNER, D M OXFD, M.R C P.
NEUROLOGIST E.M.S.

A CONCENTRATED solution of human serum was suggested as a valuable agent in reducing raised intracranial pressure by Hughes, Mudd and Strecker in 1938 They made observations on patients with raised pressure chiefly sufferers from cerebral tumour and found that the reduction of pressure continued for longer after injection of serum than after 50% sucrose solution This use of concentrated serum seems to have been largely neglected, probably because of difficulty in obtaining it Now as a result of the M.R C blood-transfusion service concentrated serum can be reconstituted from the dried serum which is prepared on a large scale for ease of storage and transport I have used concentrated serum as a means of reducing intracranial pressure in a small series of patients suffering from head injuries

METHOD

Five-times concentrated serum has been used, this is made by adding 40 c cm. of sterile distilled water to the dried solids obtained from 200 c cm of human serum There is some difficulty in getting the dried serum to dissolve in this small quantity of water but if the mixture is shaken well and left in the incubator for an hour solution will take place In each case 40 c cm of reconstituted concentrated serum has been injected intravenously It is important to keep the serum at blood temperature till the injection is given otherwise the solution becomes viscid and difficult to inject. 2–3 minutes have usually been taken for the injection of 40 c cm Since the serum is obtained from pooled blood no preliminary blood-grouping is necessary

The cases treated have been men with recent closed head injuries in whom severe headache with a high cerebrospinal-fluid pressure has been present They have previously been treated by dehydration, magnesium-sulphate enemas and ordinary analgesics Serum has only been used when these measures have failed to relieve their symptoms. Cases of this type are comparatively uncommon and care must be taken that compressive lesions are not present before serum is administered

Repeated lumbar punctures have been used to estimate fall of pressure though these have not been repeated as often as scientific accuracy would demand because of the condition of the patients This method was criticised when Hughes and his colleagues (1938) originally presented their results to the American Neurological Society and more recently by McKissock (1941), the main criticism being that the fluid may continue to escape through the hole in the dura made at each puncture and that this leakage may cause a fall of pressure Hughes and his colleagues did a control series of experiments in dogs using continuous lumbar-puncture recording and found that their results from repeated puncture were confirmed by the continuous record We have found that in late punctures after serum administration the C S F pressure may rise after an earlier fall, and this suggests that continued leakage of C S F. cannot be an important factor in determining the fall of pressure A continuous lumbar-puncture record has scientific advantages over repeated punctures, but I have not felt justified in attempting it in the rather restless post-traumatic patients to whom serum has been given

RESULTS

Blood dilution—The degree of dilution of the blood has been estimated by hæmatocrit readings All the blood samples taken from a patient have been centrifuged at the same time at the end of the period of observation so that comparable readings would be obtained Examples of hæmatocrit readings in these cases, expressed as percentage of packed cells, were.

Before serum	52	42 5	41	47	47
Time after serum					
70 min.	49	41	36	37	47
3 hr		41		43	
6 hr	46		37	44	47
8 hr.		42	40		
18 hr	52				

It will be seen that about 5% dilution of the blood had usually occurred after 70 min Sufficient readings have not been made yet to enable us to say for how long dilution continues or when the hæmatocrit readings return to normal In the last case no dilution of the blood took place

Lumbar-puncture pressure—A group of 6 patients were treated in this way Lumbar puncture pressures expressed in mm of water, were as follows

Case no	1	2	3	4	5	6
Before serum	280	200	275	235	300	300
Time after serum						
70 min	230	150	80	145		300
3 hr		180	75		250	300
6 hr	150		110		300	..

In 5 cases there was a fall in C S F pressure In case 6 the pressure was very high at the beginning and no fall was obtained, and in this case also no dilution of the blood was shown by hæmatocrit readings It is possible that a larger amount of serum should have been given to this man The most considerable fall of pressure was obtained in case 3 where it fell from 275 to 80 mm in 80 min and remained at 75 mm 3 hours after injection; 6 hours afterwards it had risen to 110 mm

Clinical results were good except in case 6 where the lumbar-puncture pressure remained unaltered and the clinical condition unchanged In 4 of the cases severe headache was the outstanding symptom and was dramatically relieved, though it was noticeable that the lumbar-puncture pressure had fallen before the headache started to decrease, usually the pain became less some 70–90 minutes after the serum had been injected, and had stopped in 2 hours In 2 cases there was never any return of headache, but in the other 2 there was some return of pain a few days later In case 5 headache was not an outstanding feature but this man was abnormally drowsy with rapidly developing focal signs due to contusion of the left parietal lobe His drowsiness became less and there was no further increase in his parietal syndrome after the administration of serum The pulse-rate remained unchanged after serum administration even when, as in most of the cases it had been abnormally slow before serum was given This supports Denny-Brown s (1941) thesis that the slow pulse-rate in these cases is not the direct result of raised intracranial pressure but is due to some other factor—he suggests medullary contusion

No untoward result of serum injection has been seen except that one man developed local urticaria in the arm into which the injection was being given The patients have been noted to be unusually constipated after treatment, presumably as a result of withdrawal of fluid from the bowel

Concentrated human serum has thus undoubtedly been of value in reducing the raised intracranial pressure and in improving the clinical condition. especially in relieving headache in this small group of acute head injuries The protein content of the injected serum is high—30–35 g per 100 c cm according to our estimations—and from the hæmatocrit studies of the blood after injection of the serum it is evident that dilution of the circulating blood occurs, presumably as a result of the osmotic properties of the serum This hydration of the blood occurs by removal of fluid from all parts of the body and the fall in lumbar-puncture pressure shows that either the tissue fluids of the nervous system or the C S F have had fluid removed from them: from which of them is still undetermined

The value of hypertonic sucrose solution has not yet been compared in this hospital with that of concentrated serum, but Hughes and his colleagues in their studies had no doubts of the greater efficacy of concentrated serum

SUMMARY

Concentrated serum was used in 6 cases of recent closed head injury as a means of reducing intracranial pressure.

Dilution of the blood occurred and in 5 patients there was a fall of pressure in the cerebrospinal fluid

The clinical results especially relief of severe headache were good and the intravenous injection of concentrated

CASE 7—A man, aged 66, with 1 year's history of typical paroxysmal neuralgia of the second division of the trigeminal nerve For the last 2 months of this period paroxysms had been occurring daily Blood-pressure 130/85 mm Hg

Treatment with nicotinic acid, 50 mg q d began on Sept 24, 1941, and resulted in complete relief after 10 days Since then there has been no recurrence of pain, this period of relief being considerably longer than any previous period of complete remission The treatment, which is continuing, has been particularly effective in this case and has considerably impressed the patient himself

SUMMARY

On the hypothesis that the paroxysms of trigeminal neuralgia are ischæmic in origin we have attempted the treatment of this condition by vasodilator drugs

We treated 7 patients—2 men and 5 women—whose ages ranged from 39 to 62 and in whom attacks had occurred over periods of 1–5 years

Nicotinic acid was used in doses ranging from 50 mg twice daily to 75 mg four times daily In every case there was improvement, sometimes amounting to complete relief This improvement has been generally maintained In 2 cases a paroxysm at its height was relieved in a few minutes by an inhalation of amyl nitrite

Vasoconstrictor drugs (adrenaline, benzedrine) were given in 3 cases, in one, adrenaline provoked an attack before treatment with nicotinic acid had begun but failed to do so afterwards, in the other 2, benzedrine increased the number and severity of the paroxysms

We wish to thank Prof J le F Burrow and Prof T Talmage Read of the University of Leeds for allowing us to see cases of trigeminal neuralgia

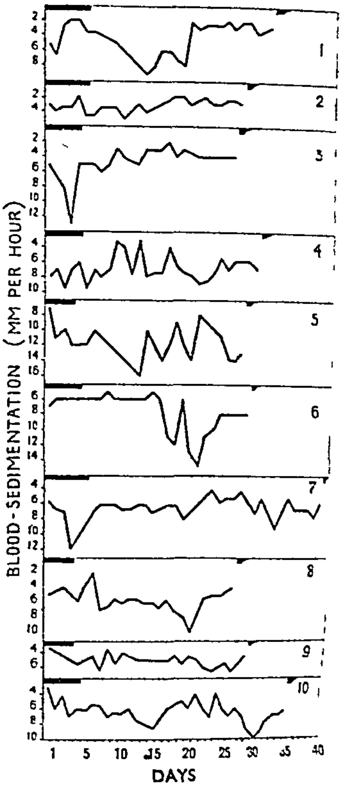
INFLUENCE OF MENSTRUATION ON SUSPENSION STABILITY OF RED CELLS

RAYMOND GREENE, D M OXFD,
PHYSICIAN TO THE E M S, SENIOR CLINICAL ASSISTANT WITH CHARGE OF ENDOCRINE CLINIC, WESTMINSTER HOSPITAL

THE measurement of the suspension stability of erythrocytes by their sedimentation-rate has become so important in checking the course of so many diseases that any factor, other than the disorder under observation, which may influence the rate might cause errors in prognosis and treatment Such extraneous influences are intercurrent infections and anæmia Infections are usually easy to exclude by clinical observation, while compensation for anæmia is easy

It was observed by Hippocrates that the sedimentation-rate of the erythrocytes of pregnant women was abnormally high, an observation which led to the bleeding of these unfortunates even into the nineteenth century This and other considerations have given rise to a suspicion that one or more of the endocrine glands may affect the rate, either by changing the fibrinogen-globulin content of the plasma proteins or by altering in some other way the electrical conditions at the erythrocyte-plasma interface Should the offending endocrine factors be either œstrone or progesterone one would expect to see a constant change in B S R during the menstrual cycle That such a change does occur has often been guessed or assumed, but only three references to the subject have been published Whitby and Britton[1] said that the sedimentation-rate is increased slightly at the menses Day[2] asked "Why do a few women show an exalted blood-sedimentation rate during their menses, whereas most women are entirely unaffected?" Lockett,[3] on the other hand, stated that the velocity reached a maximum a day or two before the beginning of menstruation I cannot find that anyone has tried to settle the question by direct experiment



INVESTIGATION

Fifteen volunteers were carefully questioned and examined Of these, 10 were finally chosen as above suspicion of harbouring any abnormality known to influence the suspension stability of their red cells With one exception they were nurses whose medical history was already known and who had previously undergone periodical medical examination Their ages ranged from 20 to 35, the average being 23 All claimed to have normal and regular periods, but in fact there was considerable variation in the length of their menstrual cycles

The B S R of each was measured every day of a complete cycle by Westergren's standard technique Correction for anæmia was unnecessary in these cases The results are shown in the figure, which make it clear that no *constant* alteration in erythrocyte stability is associated with any phase of the cycle—a fact evident without statistical analysis It is possible, however, that so short a series may fail to bring out an average change In order to test this possibility the cycle of each subject was divided into four phases phase 1, which included menstruation, was from the first day of the cycle to the midpoint between this and the presumed date of ovulation, phase 2 was thence until ovulation, phase 3 covered the first half of the luteal phase, and phase 4, the second half of the luteal phase, ending at menstruation The average B S R for each period was calculated for each subject (see table)

Case	Phase				Av	Case	Phase				Av
	1	2	3	4			1	2	3	4	
1	3 5	6 5	4	2 5	4 125	7	7 5	6	6	6 5	6 5
2	3 5	4	3	2 5	3 25	8	5	5 5	6 5	6	5 75
3	7	4 5	3 5	4	4 75	9	4	4 5	4 5	5 5	4 625
4	8	6	7 5	6 5	7	10	5 5	6 5	6	8	6 5
5	10 5	13	12	11 5	11 75	Av	6 05	6 25	6 25	6 15	6 175
6	6	6	9 5	8 5	7 5						

These figures make it clear that there is no significant variation at any period of the menstrual cycle

SUMMARY

The red-cell sedimentation-rate was measured on every day of the menstrual cycles of 10 healthy women The figures obtained show that, contrary to general belief, there is no change in the suspension stability of erythrocytes characteristic of any phase of the cycle

I wish to thank the Westminster and Middlesex Hospital nurses who allowed themselves to be subjected to inconvenience by this investigation, and Prof S Zuckerman and Mr P C Williams, D Sc, for their advice on the presentation of the figures

A CASE OF PTERYGO-NUCHAL INFANTILISM

(TURNER'S SYNDROME), WITH POST-MORTEM FINDINGS

E. P. SHARPEY-SCHAFER, M.R.C.P.
FIRST ASSISTANT IN THE DEPARTMENT OF MEDICINE, BRITISH POST-GRADUATE MEDICAL SCHOOL

AN unusual syndrome, not previously described, was reported by Turner in 1938. His 7 cases were all females and showed the triad of infantilism, webbing of the skin of the neck and cubitus valgus. Apart from the curious appearance due to the webbed neck, the main interest of this condition lies in the associated infantilism. Turner was of the opinion that the anterior pituitary was to blame and thought his cases corresponded to the Lorain-Levi type of dwarfism. The present paper describes a case who has been studied for some years and whose death from tuberculosis has afforded the first opportunity for pathological examination.

CASE-HISTORY

A woman, aged 21, was first seen on Oct. 5, 1937. Her birth had been normal and she had walked, talked and teethed at the normal age. A deformity of her neck had been noticed since birth. Secondary sex characteristics had not developed and she had never menstruated. Flushes, 3–4 a day, had been present for 3 years. She was quite intelligent but preferred childish pursuits. The mother, father and two younger siblings were normal. On examination her height was 53¼ in. and weight 112 lb. She appeared a short heavily built girl and was not disproportionate, though the arms seemed longer than normal. The photograph reproduced in fig. 1 was taken later when she had lost much weight from tuberculosis. The most striking feature was a deformity of the neck: from the mastoid process to the acromion was a well marked wing which appeared to consist of skin and subcutaneous tissue only. The trapezius muscle was normal and the movements of the neck were full in flexion and extension, while lateral movement was slightly limited. The hair line was low and the skin was freely movable over the lower part of the occipital bone. The concha of the left ear projected laterally and anteriorly, and the upper parts of both auricles were bound to the margin of the scalp. Kyphoscoliosis with prominence of the sternum was present, and there was an increase of the carrying angle of the elbow. The skin was smooth and normally moist, and there were a number of pigmented moles on the face and body. There was no axillary hair, but a scanty growth was present in the pubic region. The breasts were quite undeveloped, no glandular tissue being palpable. The labia were infantile, the vagina short and small, and the cervix was small but dilated easily when full gynæcological investigation was done. It was found that the uterus was 1 in. long and the walls very thin. Uterine scrapings were too scanty for histological section. The ovaries could not be felt. Biopsy of the vaginal mucosa showed that the epidermis was flat, and there was little cellular activity in the malpighian rete. There was considerable lymphocytic infiltration underlying the epidermis, and mucous glands were inconspicuous. Blood count and blood chemistry were normal. X rays showed a normal cervical spine, sella turcica and pelvis; the distal epiphyses of the radius and ulna were ununited, and the epiphyses of the second and third lumbar vertebræ were not fully united.

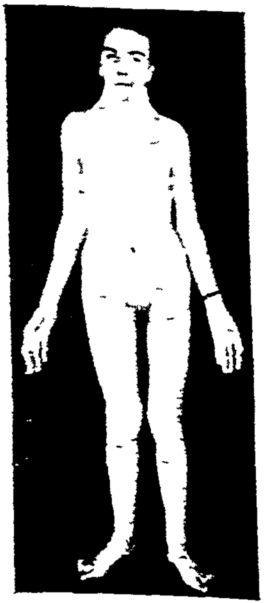

FIG 1—Turner's syndrome.

Thyroid function.—Basal metabolic rate was −7%, blood-cholesterol 160 mg. per 100 c.cm., and the electrocardiogram was normal. Injection of a pituitary thyrotrophic extract (Sharpey-Schafer and Schrire 1939a) caused a rise of temperature and pulse on the sixth day, the thyroid became enlarged and tender and the B.M.R. rose to +45%.

Carbohydrate metabolism.—A sugar-tolerance test showed a fasting blood-sugar of 71 mg. per 100 c.cm. and 130, 106, 96, 93 mg. % at 30-min. intervals after the ingestion of glucose. After 10 days on a diet containing 35 g. of carbohydrate a day, the figures were 65, 184, 230, 172, 125, suggesting a normal response of the anterior pituitary to a low carbohydrate diet (Himsworth 1939).

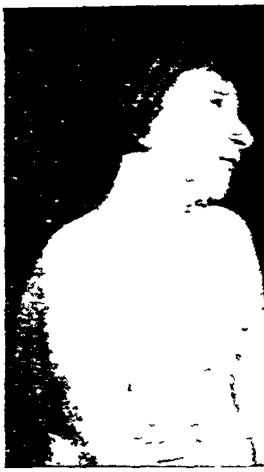

FIG 2—Klippel-Feil syndrome.

Gonadal function.—Urinary creatinine excretion was normal (Sharpey-Schafer and Schrire 1939b). A gonadotrophic pituitary extract was injected for 10 days, followed by a follicle-stimulating extract for 14 days. Biopsy of the vaginal mucosa showed slight diminution of the subepithelial infiltration with small round cells. There were no other changes. Œstradiol benzoate 100 000 I.B.U., was injected twice weekly, and 15 000 I.U. of œstriol daily by mouth were given for 9 months. At the end of 5 months the uterus had enlarged and there was intermittent uterine hæmorrhage. There was no development of the breasts or further development of body hair. After an interval of 3 months the effects of large doses of testosterone propionate on her spontaneous flushes was studied. These data have been published elsewhere (Sharpey-Schafer 1940).

In August, 1940, she was readmitted to hospital complaining of loss of weight and fatigue for 2 months. She was found to be running an irregular fever and the spleen was palpable. The diagnosis remained obscure for some time but eventually revealed itself as extensive tuberculosis of the abdominal cavity. Terminally there was a miliary spread.

Autopsy (Dr. T. H. Belt and Dr. Popjak) was performed 5 hours after death. The body was that of an extremely emaciated woman. There were many pigmented moles all over the body and two verrucæ pilosæ on the upper lip. There was a web on each side of the neck, running from the mastoid process to the acromion. The breasts were infantile. The heart and aorta were hypoplastic, the weight of the former being only 166 g. There was generalised (miliary) tuberculosis involving the lungs, intestines and peritoneum, liver, urinary bladder, left ureter and kidney, and long-standing tuberculous salpingitis with involvement of ovaries and uterus. The uterus, though filled by caseous material, was very small, 1¾ in. in length. Apart from a calcified nodule in the apex of the left lung the oldest tuberculous lesion seemed to be that of the internal genitalia. The endocrine glands, apart from the ovaries, did not show any gross pathological changes. The left ovary could not be found in the masses of tuberculous granulation tissue.

Histology.—No functioning ovarian tissue could be distinguished in the right ovary. The endometrium was destroyed by tuberculosis. The histological appearances of the pituitary gland, thyroid and adrenals were not abnormal. The mammary glands consisted of simple and branching lactiferous ducts embedded in a dense collagenous tissue. The web of the neck consisted simply of a fold of the skin without muscle.

DISCUSSION

Webbing of the skin of the neck was first described by Kobylinski in 1883. Funke (1902) and Bussiere (1902) reported single cases. Frawley (1925) described the condition in 2 sisters and 2 other females, and Chandler (1937) has reviewed the literature. Simple webbing of the neck must be distinguished from the similar webbing that may occur in the Klippel-Feil syndrome. Since the original description of this last condition in 1912, 133 cases have been reported (Rechtman and Horwitz 1940). In the Klippel-Feil syndrome synostosis of some or all of the cervical vertebræ with serum seems to be indicated in cases of recent closed head injury where the C S F pressure is high

I wish to thank Mr Harvey Jackson, director of this E M S head-injury centre, for permission to treat patients under his care, and Dr E A Carmichael for his assistance in the preparation of the paper

HÆMOTHORAX FROM LEAKAGE OF A DISSECTING AORTIC ANEURYSM

SURVIVAL

FELIX POST, M B LOND

LATE HOUSE OFFICER, WHIPPS CROSS HOSPITAL, LEYTONSTONE

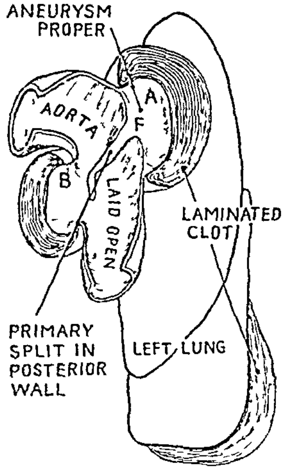
SPONTANEOUS hæmothorax has been fully described by Jones and Gilbert (1936), Hopkins (1937), Perry (1938), and Davidson and Simpson (1940), who showed that the tearing of a vascular pleural adhesion was the commonest cause Dissecting aneurysms of the aorta often rupture into the pericardium, but another common terminal event is the production of a hæmothorax, which is more often on the left side than the right Cases of dissecting aneurysm are reviewed and discussed by Weiss (1935), Glendy, Castleman and White (1937) among others and East (1939) has described the clinical features as they emerge from a survey of the literature Survival for more than a few days after the production of a hæmothorax due to the leaking of a dissecting aneurysm, as in the following case, does not seem to have been described

An unemployed man, aged 51 was admitted to Whipps Cross Hospital on March 17, 1941, his doctor having made a diagnosis of left pleural effusion In 1924 he had been diagnosed at the London Hospital as having disseminated sclerosis of two years standing, his blood Wassermann reaction was negative Subsequently his symptoms had become more severe, and for many years he had been confined to his room owing to difficulty in walking

On admission, he gave a 4 days' history of shivering, slight cough and a little sputum, which he swallowed On the day before admission while groping about in his room, he had stumbled and hit his chest in the region of his left armpit against a bedpost There was only a little pain, which had become less since the accident He had not experienced any shortness of breath He was pale and anxious, and showed signs of disseminated sclerosis—spastic paraplegia, stiffness of hands, pupil abnormalities, and rigidity of the trunk, which made examination of the back of the chest somewhat difficult Occasionally rapid pulsations were visible in the epigastrium, about 160 per minute, but these bursts did not alter the radial pulse rate of about 86 There was no fever and no abdominal rigidity In the chest there was impaired percussion note, distant bronchial breathing and bronchophony in the left lower zone of the back, suggesting consolidation of the left lower lobe, but a radiogram taken two days later showed opacity of the whole left side of the chest, which suggested fluid though there was no mediastinal displacement Clinically, some bulging of the left chest had developed, with a dull percussion note all over the back and lower part of the front, diminished breath sounds, absent vocal fremitus and whispering pectoriloquy On needling the chest, fluid indistinguishable from blood was obtained, this did not clot on standing and proved sterile on culture No fracture of ribs was seen in a further radiogram On March 25, 500 c cm of blood was aspirated from the left pleural cavity, when the patient became collapsed, pale and sweating, and the procedure had to be stopped The patient's cough ceased, he never produced any sputum Urinary incontinence and bedsores began to develop On April 8 a further 600 c cm of blood was aspirated, and at the same time 400 c cm of air was introduced into the left pleura A subsequent radiogram still showed opacity in the left lower zone with mediastinal displacement to the left No abnormal signs in the upper lung zone or about the aortic knuckle were revealed by the partial artificial pneumothorax The patient's general condition was so poor that further investigation into the cause of his hæmothorax was neither feasible nor justifiable In spite of intensive treatment with iron he became increasingly pale the bedsores became more and more offensive, and after developing a swinging temperature he died on May 23, nine weeks after admission

Autopsy carried out by Dr Keith Simpson 12 hours after death showed that the cause of death was toxæmia from extensive pressure sores secondary to disseminated sclerosis, evidence of which was found in the brain There was no fluid in the left pleural cavity, but the lobes of the left lung which showed no disease otherwise, were compressed by aseptic blood-clots One of these was lying in the costophrenic sulcus, while the other one was found in the left paravertebral gutter, partly adherent to the third part of the aortic arch This clot was laminated, and about 3 in in diameter The arch of the aorta, when opened, presented the appearances of hyaline necrosis of the media, without atheroma or syphilitic scarring There was a healed split of the intima near the end of the third part of the arch, and a short dissection, 2½ in long, had occurred, producing a local subadventitial aneurysm which was adherent to the clot previously described

In the figure points A and B of the aneurysmal bulge at the end of the third part of the aorta are complementary The wall, consisting of adventitia, leaked, causing the hæmothorax and the residual clots over lung apex and base The scar in the base of the primary split consists of media plus adventitia, the intima alone being split at all points except F



There is little doubt that, if it had not been for his disseminated sclerosis the patient would have survived this accident There is a history of slight injury to the chest, but as this occurred on the third day of respiratory symptoms, trauma was not accepted as a cause of the dissecting aneurysm or of its rupture Moreover there was no history suggestive of acute blood loss, though in all 1100 c.cm of blood was evacuated from the chest, and signs of effusion became gradually more conspicuous after admission It seems justifiable to assume that slow leakage from the dissecting aneurysm took place, and that this allowed the patient to survive the catastrophe, without producing either the dramatic clinical developments seen in most cases of spontaneous hæmothorax, or the severe pain usually, but not always (Hamburger and Ferris 1938), associated with dissecting aneurysm

I wish to thank Dr Kenneth Perry for his help and advice, Dr Keith Simpson for allowing me to make use of his post mortem findings and the diagram drawn by him, and Mr O R M Kelly, medical superintendent of Whipps Cross Hospital, for permission to publish the case

On Oct 17 Lord Rosebery opened the Paderewski Polish Hospital which stands in the grounds of a big general hospital in Midlothian and has 80 medical beds which are open to Polish civilian and military patients Surgical wards and operating theatres in the main building complete the hospital, which will also offer teaching facilities to the Polish medical faculty

" Every age is I suppose, an age of doubt from some point of view The Mid Victorian age believed in Moses and doubted Darwin The present age believes in Freud and doubts Moses "—Y Y, *New Statesman*, Oct 25, p 375 in the Waterhouse-Friderichsen syndrome, but McLean and Caffey[1] have detected meningococci in smears of the petechiæ in 15 out of 18 cases of meningococcal bacteræmia with purpura, in 3 of which hæmorrhages were present in the suprarenals at autopsy Examination of petechial smears was not done in the present case, the only evidence of the meningococcal origin of the disease being the positive complement-fixation test, but it appears to be the most reliable method of finding the organism That the disease was meningococcal cannot be doubted, however, in view of the clinical picture, the late changes in the cerebrospinal fluid and the satisfactory response to sulphapyridine

I wish to express my thanks to Dr Allen Daley, chief medical officer, L C C, for permission to publish this case, and to Dr E H R Harries, medical superintendent of the North Eastern Hospital, for advice and assistance

POSTVACCINAL AND MEASLES ENCEPHALOMYELITIS

REPORT ON TWO CASES WHICH RECOVERED

A H G BURTON,
M D LOND, M R C P, D P H, D P M
MEDICAL OFFICER OF HEALTH FOR ILFORD

J H WEIR,
M D, B HY DURH, D P H
DEPUTY MEDICAL OFFICER OF HEALTH

THE Ministry of Health reports for 1932–38 inclusive reveal only 6 cases (5 fatal) of postvaccinal encephalitis in infants under one year during this period in which Government lymph for 1,370,490 primary vaccinations was issued, 2 additional cases were notified during 1939 Encephalomyelitis is also a rare complication of measles and Boenheim,[2] reviewing 5940 cases of measles, found nervous complications in only 0 4% of which less than a third were cases of encephalitis

In the 125 reported cases of measles encephalomyelitis reviewed by Ford[3] the fatality was about 10%, and 65% of the survivors manifested residual symptoms, 8 of the cases occurred in one outbreak of measles in which some 55,000 people were affected In the 1936 measles epidemic 8 cases of encephalomyelitis were under observation in the London infectious diseases hospitals, and 3 proved fatal In view of the rarity of these conditions the following case-records may prove of interest

CASE 1

Boy, only child, aged 6 months Breast fed for two months and subsequently bottle fed on a well known proprietary brand of dried milk with the addition of halibut liver oil and orange juice No previous severe illness, accident or operation No recent or existing illness in household, brief association with contact of a case of influenza on Feb 22 Convulsions when one day old but none since Always pale and had of late been having iron tonic after feeds Primarily vaccinated by single insertion on left arm on Feb 14, 1940, full aseptic precautions being observed, 5 other children similarly primarily vaccinated about this time with same batch of lymph Of these vaccinations, 4 were successful and none developed any signs or symptoms of disease of central nervous system in month subsequent to vaccination, during which were kept under close surveillance Patient's parents had both been successfully vaccinated in infancy and mother successfully revaccinated in 1930

Five days after vaccination patient's arm became normally inflamed with slight constitutional upset and continuous crying On Feb 21 high temperature and profuse perspiration Next day squint noticed, disinclined to take bottle feeds though did not vomit On 23rd profuse salivation developed, with right sided spasmodic torticollis and elevation of right arm with flexion of forearm Other limbs extremely limp, occasional spasms of jactitation of lower extremities Later in day "clasp knife" rigidity with spastic contraction of all muscle groups appeared Child became very drowsy, apathetic and unresponsive, and uttered no sound All these signs and symptoms became more pronounced within succeeding 24 hours and on evening of 24th child was admitted to Ilford Borough Isolation Hospital

On admission temperature 99° F, pulse rate 104 Respirations 26, varying considerably in depth and accompanied by occasional intermissions and deep sighing General physique and nutrition good Weight 14 lb Lay on side with head retracted and slight opisthotonus Waxy pale and completely comatose, with no reaction to handling No abnormality detected in ears, throat, nose, lungs, heart, abdomen or urine no rash and no signs of rickets or teething Fontanelle tension slightly increased Vaccination lesion looked normal and unbroken, surrounded by inflammatory zone ¼ in wide, typical underlying deep induration Sucking reflex weakly present but swallowing reflex had disappeared Eyelids on both sides held tightly closed Both eyeballs rotated downwards and left deviated inwards Both pupils small, reacted to light, left slightly larger than right No response to conjunctival or corneal stimulation Owing to general spasticity tendon reflexes could not be obtained, abdominal reflexes absent, tâche cerebrale well marked, and plantar reflexes both extensor Kernig's sign positive Priapism present

Lumbar puncture gave clear fluid under low pressure with no excess of polymorphs or lymphocytes Cells present included epithelial, a few endothelial, and a few red blood corpuscles No organisms seen in direct smear, culture, sterile, no tubercle bacilli Protein content 100 mg per 100 c cm Sugar normal

Some days later when the eschar separated from vaccination site area was swabbed and revealed a few degenerated polymorphs, hæmolytic *Staphylococcus albus* isolated on culture

Treatment—On Feb 24 20 c cm of citrated blood from father given intramuscularly followed later by 20 c cm of citrated blood from a nurse vaccinated two months previously Sulphapyridine soluble 0 75 c cm given intramuscularly every four hours for 6 doses, after which sulphapyridine 0 25 g given four hourly by mouth On each of succeeding three days 20 c cm of citrated blood from the recently vaccinated nurse repeated and on evening of Feb 27 sulphapyridine discontinued

Progress—On day after admission slight improvement, able to take small bottle feeds On the 26th further improvement, temperature fell to normal, pulse rate remaining at 124 Now able to take feeds normally and salivation had ceased Colour paler and slightly cyanosed but coma now changing to stupor, when disturbed child made slight muscular efforts to resist and ineffectual efforts to cry Only once produced any sound Eyelids now held slightly open No recognition of light or surroundings Muscular contraction and rigidity and former signs remained unaltered, except for slight diminution in nuchal rigidity On the 27th colour better, temperature and pulse now normal and thereafter remained so Taking full feeds with avidity, crying frequently and evidently resenting being handled Appeared to respond to sounds and some appreciation of bright light held close to eyes Eyelids slightly more open and once eyes were fully opened voluntarily Transient weakness of right facial muscles Squint now intermittent Muscular spasticity unchanged Some blurring of outlines of right optic disc, left disc normal

During succeeding week generalised rigidity slowly diminished, passive limb movements were more easily accomplished, cervical rigidity, opisthotonus, torticollis and priapism disappeared and active limb movements were attempted to limited degree Ocular signs vanished and knee and ankle reflexes gradually returned, right being stronger than left By March 14 the child was trying to lift head off pillow and sit up Recovery subsequently continued uninterruptedly and by April 10, when discharged, no sign of spasticity and all reflexes normal Had gained 21 lb 5 oz since admission on Feb 24

Three weeks after discharge was examined at Royal National Orthopædic Hospital by Mr R Y Paton, who reported no signs of residual paralysis and all muscles gave normal electrical reactions

CASE 2

Girl, aged 6 years No previous severe illness, accident or operation On March 1, 1941, developed cough and 14 days later rash of measles appeared Disease pursued normal course until March 19 when aphonia developed and vacant facial expression was noticed Remained fully conscious and able to express herself and indicate needs by gesture Subsequently unable to speak despite strenuous efforts to do so On March 22 was allowed to get up but could not stand without support or perform coördinated movements with hands and arms, which had become limp and tremulous Saliva dribbled from mouth and stiffness and hyperæsthesia of legs were

2 Boenheim F *Ergebn inn Med Kinderheil* 1925 28, 598
3 Ford, F R *Bull Johns Hopk Hosp* 1928, 43, 140

limitation of movement, is present, and although numerous other congenital abnormalities may be associated, infantilism has not been reported A photograph of a girl of eleven with the Klippel-Feil syndrome is shown in fig 2 for comparison Apart from a similar webbing of the neck, this girl had kyphoscoliosis and the second, third and fourth cervical vertebræ were fused, she has since shown normal sexual development

In simple webbing and in Turner's syndrome the cervical spine is always normal The ætiology of web formation is obscure, some have attributed it to amniotic adhesions or bands, and Nageotte-Wilbouchewitch (1934) thought that it might be a form of atavism, since it occurs normally in the chimpanzee MacCollum (1938) considers that the defect may arise about the third month of pregnancy, when the ventral and dorsal surfaces of the neck are long and the mastoid process is either lateral or in a direct vertical line with the region of the acromial process, and when the skin over the lateral surfaces of the neck is shortened As the shoulders develop, it is possible for the skin to remain shortened and for a web to develop between the mastoid and acromion He points out that the symmetrical nature of this deformity favours some such theory

The clinical and pathological evidence in my case suggests that the infantilism was primarily of gonadal origin Tests of anterior pituitary function and the histology of the gland were normal, the occurrence of flushing also suggests a primary gonadal defect (Albright, 1936) It is unfortunate that the ovaries were so extensively destroyed by tuberculosis, but this infection was clearly of comparatively recent origin and could not have been responsible for the infantilism There was no breast development with prolonged œstrogen therapy, though there was considerable growth of the uterus A congenital defect in the response of mammary tissue may have been present, or, as recent work (Gardner 1940) has shown, the combined action of several hormones might have been more successful than œstrogens alone One of Turner's cases showed some mammary development with œstrogens Multiple pigmented moles were also present in Turner's first case, though no mention is made of them in the other cases

Nomenclature is always difficult in describing new syndromes, but Turner clearly deserves the credit for recognising that the condition is not simply an isolated rarity "Pterygo-nuchal infantilism" might be preferred to the hybrid "pterygium colli" of Funke It would be interesting to know if the condition has ever been seen in males or, as appears to be the case at present, whether the infantilism is always linked with the female gonad

SUMMARY

A case showing webbed neck, infantilism, cubitus valgus and pigmented moles is described

Tests for deficiency of anterior pituitary function were negative

Histology of the pituitary, thyroid and adrenal glands was normal, the ovaries were destroyed by extensive tuberculosis

It is suggested that infantilism in such cases is due to a primary defect of the gonads

I thank the Chief Medical Officer, London County Council, for permission to publish this case

CEREBROSPINAL FEVER WITH LOW BLOOD-PRESSURE

J SHARKEY, M D
ASSISTANT MEDICAL OFFICER, NORTH EASTERN HOSPITAL (L C C)

A CASE of cerebrospinal fever presenting features resembling the Waterhouse-Friderichsen syndrome has recently been treated here

Multipara, aged 40, eight months pregnant History of headache, generalised aches and pains, sore throat, rigors and vomiting, of sudden onset fifteen hours before On admission temperature 100° F, pulse rate 134, regular but of poor volume Moderate neck rigidity and positive Kernig and Brudzinski signs Nervous system otherwise normal, heart and lungs normal Systolic B P 65 mm Hg Moderately profuse petechial rash on trunk and limbs Careful auscultation of abdomen failed to reveal fœtal heart sounds Lumbar puncture gave clear fluid under normal pressure containing 3 cells per c cm, no organisms were grown from it Blood-culture negative, but meningococcal complement fixation test positive Serum-potassium 21 3 mg, sodium 292 mg and chlorides (as NaCl) 549 mg per 100 c cm After several hours the patient's condition had much deteriorated, she was now pale, weak and mentally confused, tongue dry and glazed Rash much more extensive, purpuric on trunk, with large plaques up to one inch square on buttocks and thighs

Given sulphapyridine 9 g and glucose saline 4–6 pints daily by mouth, 10 c cm of Eucortone was given intramuscularly after admission, repeated twice daily on the two following days and once daily for two further days, a total of 70 c cm

Eight hours after admission patient went into labour and delivered a stillborn male infant, autopsy on which revealed hæmorrhages beneath the visceral pericardium and into the lungs Brain, cerebrospinal fluid and suprarenals normal

After twenty four hours patient had improved slightly, rational at times, pulse slower and B P 90/50 mm Hg Left ophthalmoplegia and 7th nerve palsy had developed and there was severe headache Further lumbar puncture done two days after admission, yielded turbid fluid under pressure, containing 21 000 cells per c cm During next four days prostration and mental confusion passed off slowly, tongue became moist and clean and though chemotherapy was stopped owing to vomiting after 36 g of sulphapyridine had been given, signs of meningitis cleared up with residual left facial paresis, and cerebrospinal fluid became clear Pulse-rate dropped gradually to normal and systolic B P rose successively to 105, 115, 130 and finally 145 mm Hg On stopping eucortone systolic B P fell again to 125, and has fallen still lower during convalescence

Puerperium uneventful, except for retention of urine necessitating catheterisation for a week after delivery Rash faded completely on trunk in seven days but many purpuric plaques on buttocks and thighs broke down to form circular and oval ulcers which healed slowly and left extensive scarring Otherwise recovery was complete and patient was discharged eight weeks after admission

COMMENTARY

The unusual feature of this case was a persistent low blood-pressure with no signs of increased intracranial pressure or changes in the cerebrospinal fluid The character of the rash and the satisfactory response to eucortone make it probable that some damage was present in the suprarenals Most of the cases of Waterhouse-Friderichsen syndrome hitherto recorded were in infants and children under two years, and the extreme collapse and cyanosis of lips and extremities noted in them was not seen here, but these signs occurred in cases where massive hæmorrhages were found in both suprarenals post mortem, and were presumably due to a severe degree of circulatory failure, which was at no period well-marked in the present case

Investigation of the sodium, chloride and potassium content of the serum, in which changes are found in the more chronic form of suprarenal deficiency, are not likely to be of decisive aid in diagnosis in a disease in which vomiting and dehydration are so common The same applies to a low level of blood-sugar which has been suggested as favouring the diagnosis

A clear cerebrospinal fluid with little or no rise in pressure or cell content and free of organisms is the rule portion of the membranes which was adherent shows considerable engorgement with a good deal of interstitial hæmorrhage but little else of note The chief pathological features are the considerable focal and streaky hæmorrhage in addition to the five areas of gross hæmorrhage, the stuffing of vessels with thrombus in which the polymorphonuclear leucocytes are present in great numbers, and the entire absence of any focal accumulations of inflammatory cells or any perivascular cuffing "

DISCUSSION

The main points to be considered in this case appear to be · (1) that clinically he behaved as an encephalitis, (2) that herpes zoster was present in the unit (3) that A T T and T A B were given more or less simultaneously just before the onset of the lesion, (4) the equivocal clinical observation of herpes on the lips accompanying the febrile onset of the illness, (5) that he had received sulphapyridine, and (6) the histopathological findings of a brain in which a toxic rather than an inflammatory reaction were the main features

Russell Brain[1] has carefully reviewed the literature on zoster encephalitis and although it is tempting to include this as such a case the autopsy findings are dissimilar and a physician who saw the patient at the time was satisfied that the herpes was herpes labialis Nevertheless when seen in this hospital the fading vesicles extended well on to the cheek and angle of the jaw and were judged to be zoster The administration of A T T and T.A B simultaneously is known to be provocative of intense reactions and the onset of this case twelve days later shows a suspicious analogy to known cases of postvaccinal encephalitis as regards the latent period

The actual type of response to virus infection seems to be of two varieties, according to Adler,[2] who has reviewed 100 consecutive cases diagnosed as acute encephalitis out of a total intake of 368 000 patients at the Boston City Hospital from 1929 to 1938 Only 70 of these satisfied her *criteria for inclusion as unequivocally* proven cases and in only 19 was an autopsy performed The pathological findings demonstrated two clear entities—a toxic and a focal variety The toxic variety was characterised by signs of diffuse cerebral involvement with a normal cerebrospinal fluid and perivascular hæmorrhages, but without focal leucocytic infiltration or demyelination In the focal variety there were clinical signs of localised neurological lesions, with an abnormal spinal fluid and focal cellular infiltration and occasionally demyelination The case here described seems to belong to the group of toxic encephalitis, and in an analysis of Adler's case material both types occur as postinfectious phenomena These are her figures

	Cases	Deaths
Postinfectious groups (following mumps, rubella, &c)	30	13
Following exogenic poisons (alcohol, lead, &c)	8	1
Infectious encephalitis (mastoiditis, typhus, &c)	11	7
Acute lethargic	4	1
Other cases	17	5

The possibility that sulphapyridine may itself produce cerebral symptoms has been raised by Johnstone and Forgacs,[3] who observed that in some cases of cerebrospinal fever signs of cerebral irritation persisted or increased after the cerebrospinal fluid had become normal Unfortunately no autopsy was done on their two fatal cases In the present case there could be no question of overdosage, but according to Johnstone and Forgacs cerebral irritation may arise from moderate dosage of sulphapyridine It seems, then, that this possibility cannot entirely be excluded here Similarly it is not possible to exclude a toxic encephalitis secondary to a mild pneumonia though the autopsy gave no support to the clinical findings of pneumonia.

SUMMARY

A fatal case of toxic encephalitis is described in a man of 19 The lesion may have been secondary to a mild pneumonia, to zoster, to the injection of antitetanic serum and T.A B vaccine, or to sulphapyridine therapy.

Medical Societies

ROYAL ACADEMY OF MEDICINE IN IRELAND

AT a meeting of the Section of Medicine on Oct 10 with Dr A R PARSONS in the chair an address on

Water Deficiency

was read by Dr R H MICKS the president of the section He did not include the dehydration of surgical shock (without fluid loss) or the dehydration caused by extensive burns for so much knowledge of these two subjects is now being acquired that it is too early to lay down systematic teaching But it is important to try to arrive at a systematic teaching about dehydration due to diminished water intake or abnormal water-loss The phenomena of water deficiency may, he said be divided into three stages—first, those of the falling water-reserve symptomless except for the loss of about a twentieth of the body-weight, second, those of dehydration without circulatory collapse, the symptoms of which are a dry tongue loss of elasticity of the skin hæmoconcentration, and beginning impairment of renal function · third, dehydration plus circulatory collapse The aim must be to recognise the first stage because the proper treatment of dehydration is to anticipate its onset, as can easily be done by careful measurement of the water balance or, in the infant, frequent weighing When dehydration is due to excessive loss of body fluids sodium chloride is as much needed as water In dehydration plus circulatory collapse the intravenous route should be used, and at times hypertonic saline is required In general the solution administered should be normal saline but there is evidence that for rapid rectal absorption 0 12% saline is better Glucose solutions are not necessary except when parenteral feeding has to be maintained for a long time, and sometimes in diabetic coma There is little reason to think that either special alkalinising fluids or fluids containing calcium or potassium salts are useful, except possibly in certain rare cases The intravenous route is really one only required in emergencies In many cases fluid can be administered by mouth or nasal tube Rectal drip is satisfactory in many cases and enough fluid can be given by that route to maintain life and compensate for a considerable abnormal loss Intramuscular administration has been used successfully in some large clinics Subcutaneous administration of large volumes of fluid is now but little practised, and Dr Micks asked for the experiences of those who had used it Intraperitoneal administration is, he thought, usually unsatisfactory because little fluid can be given

Prof W. R FEARON wondered whether people drink enough water and whether doctors are giving enough of it to their patients Water deficiency is usually a question of salt deficiency and salt balance If the cell membrane is complete the ions do not tend to escape readily from the cell There is no mechanism equivalent to that of thirst to tell one when there is too much water in the body If one knows the osmotic pressure of the urine one can draw the osmotic curve from hour to hour This will show the state of water balance at any time The treatment of dehydration is physiologically the administration of saline Far more harm is likely to be done by giving too little water than too much

Prof W J E JESSOP referred to the relationship of water to treatment with the sulphonamides Water restriction in such cases is dangerous on account of the formation of drug crystals in the kidney.

Mr SETON PRINGLE president of the academy said that surgeons recognised earlier than physicians the possibility of severe and perhaps fatal dehydration In every major operation Arbuthnot Lane used to insert a needle under each breast and give two or three pints of saline. This was a great help in the first and second stage of dehydration, though it was quite useless in the third stage Mr. Pringle had found saline without glucose satisfactory Rectal drip has been the routine method for many years, but in many patients it proves uncomfortable and inconvenient If serious dehydration is feared this method is tedious. A reservoir of saline is now used instead of the drip This is connected with the noted During next few days hands and arms increasingly rigid Frequent attacks of crying on March 28 On 29th developed intense pain in legs and periodic screaming attacks between which lay stuporose

Admitted to hospital on night of March 31 in stupor Colour poor Lay on side with slight opisthotonus Temperature 99 4° F , pulse rate 84 When examination was attempted became extremely violent and resistant, screaming with a husky voice of metallic timbre Apart from slight congestion of fauces, physical signs limited to central nervous system Pupils reacted to light and accommodation Well marked tremor of limbs with some rigidity , stiffness of spinal and neck muscles with slight opisthotonus Kernig's sign weakly present on both sides , reflexes all somewhat exaggerated, with bilateral ankle clonus. Lumbar puncture gave bloodstained fluid under normal pressure and on this and two subsequent occasions, 3 and 7 days later, examination report normal except for blood cells accounted for by difficulty of controlling child during operation During night of admission, erythematous rash appeared on arms and legs, with petechial spots on knees By next morning temperature and pulse normal and remained so thereafter, but child excessively restless and violently resistant, with frequent attacks of screaming , required constant supervision and restraint to prevent her throwing herself out of bed Head retraction, opisthotonus and limb tremor more definite Later in day developed repetitive cycle after throwing herself about and screaming for three minutes, during which arm and hand tremors, head retraction and opisthotonus were accentuated, had an interval of two to three minutes when lay quietly supine with outspread legs and arms, eyes and mouth wide open

Treatment —On admission put on fluid diet and given sulphapyridine 0 5 g four hourly by mouth, later augmented by sulphapyridine soluble 3 c cm intramuscularly On April 2, 12 c cm citrated whole blood given intramuscularly and on 3rd, 4th and 5th 20, 20 and 10 c cm of measles convalescent serum given Restlessness controlled by large doses of syrup of chloral and bromide

Progress —Slight improvement on April 4, when limb rigidity and tremors were less, opisthotonus and nuchal rigidity diminished and irritability not so extreme Now appeared to be conscious and would follow moving object with eyes Periodic attacks of screaming still occurred and still resentful of handling Improvement was maintained and speech, at first limited to whispering with unnatural lisp, regained on April 6 Cerebration at first slow and irrational but improvement comparatively rapid and recovery uninterrupted and uneventful Discharged on April 20 When re examined on May 7 no signs of disease of central nervous system or evidence of mental impairment elicited According to parents only abnormality was slight tendency to fidget, but speech clearer and more distinct than before illness

DISCUSSION

While the use of blood or serum from recently vaccinated persons or measles convalescents is a well-recognised method of treatment in such cases, few examples of the successful administration of sulphanilamide or sulphapyridine are recorded Although the value of sulphapyridine in virus infections generally is doubtful, it was felt that since it has been of benefit in certain diseases of virus origin, it should be employed in an attempt to augment the effect of serotherapy It is interesting to note that Miller and Wray[4] have recently applied this principle to the treatment of poliomyelitis

Since the fatality-rates in these cases vary considerably in different age-groups and in different recorded series, and spontaneous recovery does occur, it cannot be claimed that the favourable therapeutic response was achieved by the agents employed acting either singly or in combination Nevertheless, in view of the extremely grave condition of the children, the first of whom was in an age-group for which the fatality is high, the extensive involvement of the central nervous system and the rapid progression of the disease process without any evidence of amelioration until treatment was instituted, some encouragement is given for the future employment of the method

SUMMARY

A boy aged 6 months, with postvaccinal encephalitis, was treated with sulphapyridine plus intramuscular injection of blood from his father and from a re vaccinated nurse

A girl aged 6 years, with encephalitis following me was treated with sulphapyridine plus intramuscular blood and convalescent measles serum

Both recovered completely

MAJOR, R A M C , LATE SENIOR ASSISTANT PHYSICIAN,
WOODSIDE HOSPITAL

A SOLDIER, aged 19, belonged to a unit in which three men developed typical zoster The first reported si Nov 30, 1940, the second on Dec 20, 1940, and the early in the New Year 1941 The patient enlisted on De 1940, received his first antitetanic injection on the 21s first T.A B injection on the 23rd and his second T injection on Jan 3 Twelve days later he felt ill, compl of nausea and headache, vomited once or twice and su from diarrhœa On Jan 17 he felt shivery and reported sick and was put to bed ; his temperature 103° F Next day he had slight head-retraction an headache was worse , a few herpetic lesions were note diagnosed as herpes labialis On Jan 19 he complain slight breathlessness and his general condition arouse suspicion that he might be developing pneumonia He therefore given 6 g of sulphapyridine in 48 hours, and arra ments were made for his admission to hospital There evidence of pneumonia could be found, but he had a sputum which was sometimes blood streaked (He had a slight cough with sputum for the previous month, a sister had died of phthisis) He was once more pu sulphapyridine as a precaution, receiving a further 7 g next three days On Jan 21 he had a sudden tran impulsive outburst recorded as a " hysterical attack " day he was confused and restless, and was transferred military hospital

On admission he was in a restless, delirious, very conf out of touch with his surroundings, and resistant t nursing and medical attention There was slight rigidity and a positive Kernig's sign , the optic discs sh a little haziness of the nasal margins , the cerebrospinal was under moderate pressure and contained 7 lymphoc per c mm Blood count showed 18,000 leucocytes per c There was a fading crop of herpetic vesicles on the left of his cheek A further 7 g of sulphapyridine was between Jan 25 and 28 He became more restless, requ sedatives, and two areas of purpuric staining appeared his right shoulder and sacrum On the 27th he had a J sonian seizure, after which his condition changed to a coma On the 28th he had two further convulsions, and plantar responses were extensor He died on the 29th

Autopsy —No abnormality in dural or accessory sin Membranes were rather pink and congested, and in temporo parietal region were adherent and manifestl flamed over an area 2 in square , apart from this appeared somewhat bulky and œdematous Cut surfac brain slightly pink , five areas of colliquative hæmorr necrosis, two in one hemisphere and three in the other T ranged from ½ to 2 in across and were filled with a purple liquid Lieut I B Gartside, R A M C , reporte the sections as follows, and Prof M J Stewart has k confirmed his findings

" Several blocks of the brain tissue have been exami Nowhere is there any suggestion of perivascular cuffing any other focal accumulation of inflammatory cells T is some generalised œdema of the brain tissue, but this is well marked In all the blocks examined there is much and streaky hæmorrhage scattered throughout the tissu addition to the gross hæmorrhage seen by the naked eye large block, which shows relatively little change in the b substance, shows a striking feature in the meningeal veins vesicles lying in the sulcus which runs through section, and in the capillary and venular channels in substance of the brain itself These are all distended thrombus in which polymorphonuclear leucocytes are pre in large numbers (It will be remembered that there w leucocytosis of 18,000) This block also shows the s abundance of focal and streaky hæmorrhages, with s necrotic changes in the brain tissue in relation to th hæmorrhages, which is seen in all the blocks examined

THE LANCET

LONDON. SATURDAY, NOVEMBER 8, 1941

THE WARD DRESSING

INFECTED war-wounds may be divided into two broad categories first, wounds infected outside the hospital ward, and these are for the most part infections with the anaerobic sporing bacilli, *Clostridium tetani* and the gas-gangrene group , secondly, wounds infected inside the hospital ward where the principal pathogens are the pyogenic bacteria—staphylococcus and streptococcus and the coliform bacilli including proteus and pyocyaneus These pyogenic organisms are found in only a small proportion of open wounds examined on admission to hospital—the figures have been 5–6% in the present war and 15–20% in the last —but after a week's stay in hospital the proportion of infected wounds may exceed 50% and increases with further residence to 70–90% *Streptococcus pyogenes* is the most dangerous of the pyogens because of its great invasiveness, but the coagulase-positive staphylococcus, which in the past year has been the most frequent pathogen found in war-wounds, may also produce much chronic invalidity if it gets access to bone It is true—and perhaps unfortunate—that infection produces little evidence of local or systemic upset in many wounds, particularly if they are shallow and draining well, and does not greatly retard healing, so that a complacent surgeon may regard such infection as innocuous But once in a while an unfortunate " accident " occurs—a new patient develops cellulitis or septicæmia, signs of osteomyelitis appear in a case of compound fracture, nurses go off duty with septic fingers and sore throats, and the surgeon realises too late that infection is rampant in the ward

It was to the problem of preventing these tragic consequences of wound-infection that certain teams of surgeons and bacteriologists in Hertfordshire addressed themselves during the past winter, and a direct result of their researches is an excellent memorandum,[1] published jointly by the War Wounds Committee of the M R C and the Committee of Sector Pathologists with Dr E T C SPOONER as editor In it the problem of hospital infection of wounds is clearly set forth and practical instructions are given for its prevention If it be granted (and the circumstantial evidence is very strong) that pyogenic infection of open wounds takes place mostly in the hospital ward, the possible sources must be defined and controlled and the channels of spread blocked The principal sources are wounds already infected, the air-passages of patients and ward personnel, and the dust of the ward which has become infected from the first two sources The channels of spread are direct transference by hands, instruments and dressings which become bacterial carriers from contact with already infected wounds or respiratory tracts, droplet infection from the nose or mouth of attendant or patient (5–10% of adults are throat carriers of *Strep pyogenes* , 30–40% are nasal carriers of *Staphylococcus aureus*), and air-currents carrying infected dust or droplet-nuclei Obviously if the proportion of infected wounds increases, dust and air become more heavily infected, sore throats appear and a vicious circle sets in In the infection of wounds, it seems probable, though the point has not been proven that direct transference by infected hands or instruments is more important than droplet or aerial infection The latter two channels can be largely blocked by efficient masking of all ward personnel plus the maintenance of silence among the patients and a still atmosphere during the period of the dressings Bed-making, sweeping and dusting must be completed at least an hour before dressings are begun, windows and doors should be kept closed to minimise air-currents, floors may be treated with spindle-oil to adsorb the dust, and any movement of bedclothes must be done gently and slowly

For the control of contact infection a technique which for many will mean a radical revision in ward wound-dressing is recommended and described in detail in the memo The key-points in this ritual are that the hands of the dresser are to be regarded as at all times infected, while the wound and the surrounding skin are to be likened to a plate of culture medium —that is, a surface very susceptible to infection and therefore to be uncovered for the shortest possible time, and, the memo might have added, as infrequently as possible Gone are the days when wounds are gaily laid bare for the round of inspection by the big white chief and his retinue of maskless followers Instead there is to be a dressing team, each member well versed in his or her own duties, and each wound must be inspected and re-dressed before the next is dealt with The team consists of the dresser (preferably the house-surgeon), the trolley-attendant, a trained nurse who is responsible for the care and sterility of instruments, dressings bowls and so on and a " dirty " assistant to lend a helping hand in removing bandages or holding a limb, and to lift the lids of the bins for discarded dressings , all dressings are discarded but the bandages and outer dressings are salvaged for re-use After the outer dressing has been removed by hand the inner dressing is changed by the dresser with long instrument forceps in hands that are washed and dried but not ' scrubbed up " Every step is designed to prevent the transference of infective material from one wound to another by hands, instruments or dressings For the sterilisation of instruments and the various receptacles—which should have lids—boiling in water in a ward-steriliser big enough to take the largest vessels is recommended , 2% soda should be added to prevent rusting, and scalpels may be so sterilised without detriment provided their blades are wrapped in lint or placed in a zinc rack Once sterile, instruments can be kept in a dry sterile dish with a cover, or if this method is not convenient they should be immersed in liquor formaldehydi chirurgicalis[3] rather than lysol or spirit Much practical instruction is given about the irrigation of wounds, chemical disinfectants, masks, sterilisation, and cleansing of baths, and particular attention is directed to the danger of cutting and changing plasters in the ward, for plasters usually teem with bacteria both inside and out One of the most sensible suggestions is that nurses should have a short *practical* course in bacteriology which will bring home to them better than many abstruse lectures what infection means a view which is borne out by Dr JANET WELCH's experience in Africa (see p 574) rectum through a very wide tube and the saline is only taken up from the bag as it is needed, so that the rectum never becomes distended or uncomfortable

[1] Prevention of " Hospital Infection ' of Wounds M R C War Memo No 6 H M Stationery Office, *6d*

[2] Borax 1 5 solution of formaldehyde 2 5, phenol 0 4, water to 100

Dr Geoffrey Bewley referred to the giving of nasal fluid to unconscious patients and said that in these cases it is frequently a case of giving food as well as fluid The patients are given eggs and sugar by this route Life can be preserved for months by giving fluid through the nose

Prof T W T Dillon said that one of the most important things is to have some easy test by which to know when enough water has been given and the water depots are full If the specific gravity of the urine is taken in these cases it will be observed that water repletion coincides with a sharp fall in the specific gravity

Dr R E Steen said that there were certainly definite indications for the intravenous drip method in young children

Mr J C Flood said that until two years ago there was a tendency to give too much water Patients were given transfusions of water under every condition of surgical collapse It was then considered that this was being overdone Of the importance of water in the right class of case there can be no doubt It is necessary to distinguish between dehydration due to water going out of the body and that due to water coming out of the blood channels There is a considerable chance of the patient being overdosed with water if he is suffering from straightforward shock associated with a water shift out of the blood-vessels into the tissues There is no entirely satisfactory and reliable therapeutic test to show when enough water has been given When a patient is receiving postoperative transfusions and salines a record must be kept of the total fluid intake and excretion every day

Dr A W Spain thought the intravenous route unsuitable for a doctor faced with an emergency away from a hospital In such cases the subcutaneous route is very efficient It is astonishing how rapidly a patient will absorb fluid if a pint is put under each breast This can be done without causing the patient any inconvenience

Reviews of Books

Surgery of the Heart

E S J King, M S Melb, D Sc, F R C S, F R A C S, major A A M C, honorary surgeon to out patients, Royal Melbourne Hospital London Edward Arnold Pp 728 50*s*

Versatility and thoroughness do not always go hand in hand, but here is an exception During the past twenty years Major King's interests have ranged over surgery and pathology, from teeth in dermoid cysts to successful thoracic œsophagectomy for carcinoma, and now he succeeds in concentrating a vast and admirably documented quantity of information that bears on every phase and aspect of cardiac surgery The book begins as it should with a clear, brief account of the heart's development, abnormalities, anatomy, physiology and pathology Two welcome chapters explain orthodiagraphy, kymography, tomography, and finally, electrocardiograms, their shape and value All the eggs—those war-time symbols of what is commonplace but unfamiliar—are thus in one convenient basket Major King goes on to deal with experimental investigations, with the special surgical problems created by disease or injury of the heart or pericardium The broad impression left is one of swift advance—encouraging, brilliant, tentative Time must pass before we can choose, for example, with confidence the best surgical means of treating angina pectoris and the most suitable cases for treatment Methods include those which seek to interrupt the conduction of pain and those—more numerous—aimed at removing the cause, the second group are designed to increase the vascularity of the myocardium, either by means of grafts of muscle and omentum, or else by opening up the rather grudging inosculation of cardiac vessels This last method links up with the well-known work by Makins on simultaneous ligature of vein and artery, Blum and Gross have found that when the coronary sinus has been occluded, they can then, with the heart congested, tie a coronary artery at a point where ligation would otherwise cause death

In discussing quasi-separate blood-supplies to the half-dozen layers of ventricular muscle the author argues that the fibrosis caused by infarction of one or other of these layers is likely to offer a barrier through which new vessels brought by a graft might be unable to grow The fibrosed layer itself is often past salvation, and even if new vessels do penetrate compromised heart muscle, can we be sure that in *the living subject* there will be a flow through them towards the heart and not away from it ? On these and many other points he brings his own investigations to bear He suggests that too little attention is paid to the effect of merely opening the pericardium, for pain in some of his cases has been relieved before new vessels could possibly grow into the heart Such relief is linked perhaps with the achievement of O'Shaughnessy and McCunn who managed to improve exercise tolerance in racing greyhounds by liberating their large hearts from pericardial restraint

Satisfying indications for treating pulmonary emboli by operation are not yet even in sight, the surgeon must still wait till the red warning gives way to the green signal of death And while it is certain that recuperable cases are being lost through an almost pandemic blight of unprepared defeatism, it is likely, too, that operation is often a superfluous coup-de-grâce We shall be in much better position to judge of this and other cardiovascular procedures when we possess many more accounts of failures, Nystrom wants careful records of them all In the meantime we can study how to simplify, or even extend, the scope of intervention by removing clot with aspiration instead of forceps Major King gives too little detail of operation for these emboli, he does not mention the screen of thick fat often found in front of the pericardium, a screen which may well confuse tyros, who are told to expect " a white and shining membrane " as soon as " the pleura is swept laterally " And " sweep," too, must be carefully qualified, the act needs no dash and plenty of method

Cardiac-valve surgery is for the moment at a standstill in clinical practice, operation has only achieved success in 3 cases with mitral stenosis—Tuffier's in 1914, Cutler's in 1923, and Souttar's in 1925 In the first and last dilatation was made with a finger, while a tenotome was used in the other, and who knows how much of the improvement was due to the mere opening of pericardium ? It would be improper to criticise a comprehensive, disciplined work on the score that the fascination of the subject is kept in abeyance, but we cannot help wishing the author had followed the practice of old writers and given us more loving detail (should one say the lowdown ?), for example, on the toothpick found in the heart Meanwhile he has produced for those concerned a quite indispensable book

What Price Alcohol ?

Robert S Carroll, M D, medical director, Highland Hospital, Asheville, North Carolina London *Macmillan* and Co Pp 362 12*s* 6*d*

Dr Carroll certainly knows his alcoholists from infancy upwards and illuminates their progress through life by many a tell-tale case history He appears however to indict alcohol for all degenerative trends in modern American civilisation, rather than to regard alcoholism as but one symptom of the neurotic's failure to face up to life's demands

An interesting thesis, developed at length throughout the book, is that faulty diet is the fundamental defect in the average alcoholist In the author's opinion the frequent restless gobbling down of everything from hot-dog to chocolate induces a " vitality-deficiency " and a " food-crave " which develop into a demand for the quicker satisfaction afforded by alcohol He advances a " blood-brain-barrier theory," according to which the function of the choroid plexus is to filter off from the blood deleterious substances which would injure neurones and synapses if allowed to reach them Products of hyperalimentation alter the permeability of the barrier and thus are indirectly responsible for dysfunction of the higher cerebral centres Brain tracts of poor quality will be disorganised more easily than those of robuster heritage by barrier-passing toxins Hence the distinction between those who can and those who cannot carry their liquor On treatment Dr Carroll's general advice is eminently sound he keeps insistently before the patient the maxim " You have come here to be taught to live without alcohol in any form at any time " He shows clearly that the attainment of this freedom involves nothing less than re-education of the addict personality uncongenial job without being told the reason, so they went sick, as soon as they learned why they were needed they complied without hesitation We are trying to get the best work out of a race of people who resent dictation, and we set about it by tiring them out and telling them nothing We have the method, not the men and women, to blame for absenteeism

MALARIA BROUGHT HOME

THE War Office pamphlet[1] on the treatment of malaria in people returning home from malarious areas is a timely reminder that we are likely to see many such cases during the next few years Many people who contracted, or thought they contracted, malaria during the 1914–18 war are convinced that they still suffer from the disease This is unlikely, for it seems that malignant tertian malaria rarely persists for more than a year or two after return from the endemic zone, although simple tertian and quartan malaria may on occasions last longer There are exceptional cases, particularly of quartan infections, where the disease goes on giving trouble for long periods, but it is unwise to assume that any febrile disturbance in a person who has once had malaria is necessarily due to a relapse The only way of establishing the diagnosis is by the recovery and recognition of malaria parasites, clinical examination alone is open to grave fallacy Again, patients presenting a remarkable variety of symptoms and signs, quite unlike those of the classical malarial paroxysms, may be found to have pyrexia with parasites in the peripheral blood, and a few doses of an antimalarial drug will produce an astonishingly rapid alleviation of their trouble. When facilities do not exist for the microscopical diagnosis of the disease before treatment is begun, blood films should at least be made for later study The so called therapeutic diagnostic test may be gravely misleading, and should never be relied on There is here one difficulty which constantly obtrudes itself in the study of this condition—the almost universal practice adopted by people who have lived in endemic areas of taking antimalarial drugs whenever they feel off-colour A few doses of such drugs may well render the microscopist's task hopeless for the time being In such cases there is little risk in stopping the drug and awaiting the reappearance of parasites in the peripheral blood before proceeding with systematic treatment The diagnosis will then be established and treatment can at least be begun on a sound foundation

Having established the diagnosis, the next step is to deal with the attack The War Office pamphlet advocates the consecutive employment of three drugs. a salt of quinine by mouth in ten-grain doses thrice daily for two days, mepacrine hydrochloride (the British equivalent of Atebrin) by mouth in doses of 0 1 g (1 tablet) thrice daily for five days, and finally, after a two-day interval, pamaquin (the British equivalent of Plasmoquine) in doses of 0 01 g (1 tablet) thrice daily for a further five days In this course the quinine salt is given first, since it is generally agreed that the action of quinine on the parasites, and thus on the clinical condition, is more rapid than that of any other available drug The mepacrine sustains the therapeutic action and arrests the attack. Pamaquin, however, has little or no effect on the paroxysm but is given after this has been arrested, for when so given it is believed further to reduce the liability to subsequent relapse This tendency to relapse is believed to be considerably greater after an attack has been treated by a single drug (either quinine or mepacrine) alone In civil practice in this country there may be occasions when it is impracticable to follow this suggested course of treatment One drawback is the necessity for keeping the patient in bed virtually throughout its duration—he should be confined there during and for some days after the pyrexia, and he should remain there during the exhibition of the pamaquin Another may well be the expense and the lack of ready availability of mepacrine and pamaquin A third is the possibility of toxic manifestations, especially liable to be caused by pamaquin On such occasions there seems no reason why resort should not be had to the safe, cheap and universally procurable quinine preparations used in the treatment of innumerable cases in the past, and today still widely employed both here and elsewhere It must be remembered that, particularly in the case of simple tertian and in quartan malaria, relapses do occur in many cases after a course of quinine alone, and possibly the relapse-rate is higher than that following a sequence of drugs, completed by a course of pamaquin, but this does not necessarily mean that quinine alone is not a most valuable drug A method of treatment with quinine is suggested in the pamphlet, but another much employed consists of the oral administration of ten-grain doses of quinine sulphate in acid solution (Ac sulph dil ♏xv in a tablespoon of water) thrice daily for three or four consecutive days This will arrest almost any attack of malaria and clear the parasites from the peripheral blood of nearly every case If this course is followed by the administration of the drug in similar doses on two consecutive days each week for a couple of months most early cases of malignant tertian malaria will not relapse Such, unfortunately, cannot be said of simple tertian and quartan cases Where relapses do occur in these the course can be repeated Advantages of quinine are that it is effective in producing rapid clinical cure of the acute attacks, and that when this has been achieved the patient can continue with his ordinary vocation throughout the remainder of the course At present many seamen on merchant and other vessels are being treated on these lines, and the period of their disability ashore is thus reduced to a few days They can then return to sea, provided they continue to take the drug as directed Many claim to be unable to take quinine, but in fact nearly everyone can do so, in the doses recommended, without any symptoms except temporary deafness and tinnitus

The observations in the pamphlet on the intravenous and intramuscular injection of quinine deserve particular attention Their routine and repeated use is rightly condemned, and due care must be exercised when using the intramuscular route to avoid periosteum and bone, large nerves and vessels, if disastrous results are not to follow Intravenous quinine is potentially dangerous and should be given only in carefully selected cases and with extreme caution The type of case requiring parenteral administration is the one in which the drug either cannot be taken or retained by mouth, or in which

---

[1] Notes on the Treatment of Malaria occurring in Individuals returning from Service in Malarious Areas H M Stationery Office 1941 Pp 6 1d

Their intelligent cooperation, essential for success in countering cross-infection in wards, can only be obtained if the rationale of new procedures is explained to them, and a simple summarised version of this memorandum might well be made available to nurses

If the recommendations in this pamphlet seem to some surgeons rather elaborate, with a smack of the laboratory about them, let them not on that account dismiss them as impracticable or unnecessary Infection of open wounds is a menace to be constantly guarded against, and it is illogical to use a less strict technique in dressing these susceptible wounds in the ward than is used for less vulnerable tissues in the operating-theatre That the new technique is both practicable and effective has lately been shown by McKissock, Wright and Miles,[3] who with it reduced the incidence of hospital infection in air-raid casualties from 31 3 to 2 2% in improvised E M S wards Local sulphonamide prophylaxis and other new methods may help to minimise hospital infection of wounds but there can be no gainsaying the soundness of the principles enounced in this memo, particularly for the dressing of open wounds It should be read and digested by every surgeon, house-surgeon, hospital bacteriologist and surgical ward sister

ABSENT FROM WORK

A decent craftsman, seen by his doctor on a Sunday afternoon, complained that he was dead to the world , he had been working for six days a week from 8 A M to 9 P M and on Sundays from 8 A M to 4 P M , he has had two days off in the past year Another tired out labourer hopes he will not be sent to the docks for there they work 12-hour shifts seven days a week An A T S girl, coming home on 48 hours' leave, spends the first 36 hours of it sleeping These are three relatively trifling examples of the fatigue which must be holding up production The Ministry of Supply might take as their slogan "Too Long Hours mean Short Output," and every works manager should have it hung over his desk

Unfortunately when hours are reduced the output does not rise immediately , there is a relatively long period of adaptation before the workers recover from fatigue and begin to improve their standards Naturally the lag also operates in the reverse direction, so that an increase in hours will produce a greater output for the first few weeks—until fatigue sets in This must be so , the human body cannot be switched straight into a different gear like a machine These two equal and opposite lags make it difficult to convince the denser and more old-fashioned works managers that shortened hours will increase production , and so the damage goes on Many of the workers themselves recognise the fallacy in long hours and take a day off when their fatigue becomes too great Thus there are constant complaints of absenteeism in industry at a time when absenteeism can harm us all

But fatigue, though the most important, is not the only thing which keeps people away from work There is always more absenteeism among women than among men, and in war-time the increase in absenteeism among women is proportionately much greater Some of the reasons for this appeared clearly in discussion at the second session of the Women's Parliament, reported in our issue of Nov 1 (p 537) The greatest increase is among married women who would not normally be working in factories These still have their ordinary work to attend to they must still keep the home clean, buy food for their families, cook it and clear it away It might be supposed that when both partners were out at work both would share in domestic duties in the evening ; but this does not seem to be so Etiquette among manual workers enacts that a man cannot help in the home without being looked down on by his mates This false pride has been found to be particularly prevalent in the north country where a man may help his wife by lighting a fire, but must not lend a hand in cleaning the house or washing up—the bulk of the housework Even if the man is out of work and the woman is supporting the family his status must be preserved, and he cannot even do the household shopping without loss of prestige Shopping nowadays is not a task which can be performed in a few odd minutes, so women take time off from the factory to do it—they have to Absenteeism has been considerably reduced in factories which have added household goods to their canteens so that women can do their shopping during the lunch break Even so, time must be borrowed to clean the house, give children their meals, or look after a husband home on leave This piling up of tiring duties renders women more liable to breakdown than men, and illness is the second most important single cause of absenteeism among women Travel difficulties increase fatigue for both sexes, as do nights made sleepless by raids or by civil defence duties Sometimes raid damage adds heavy and dismal salvage work to the day's toil

Unpunctuality and slowness in starting work cause nearly as much loss of output as absenteeism and it is noteworthy that many women prefer to stay away altogether than to clock in late, feeling that they might as well hang for a sheep as a lamb This prejudice, foolish as it is, has to be taken into account Many women and young people are without ambition and remain untempted by the thought of promotion or more pay Moreover in many factories the workers —men and women alike—have little sense of sharing in the war effort , the idea that the Forces are depending on their work seems remote and unreal This attitude is often coupled with the independent Englishman's belief that his boss "knows nowt" and is making a hopeless mess of things This view, often mistaken, springs from ignorance of the problems to be overcome and therein lies the kernel of this matter In industry and local government there is too little give and take of information, too few committees on which workers and officers meet to exchange views and discuss policy The discontent often found among those serving public bodies springs largely from the fact that they are treated as pawns and never consulted as reasoning people The same applies in industry Workers who are told the plans of their employers—who have the background of special demands explained to them and who understand not only what their factory is out to do but also what difficulties stand in the way of success—are anxious to help Those who are treated like children and kept in the dark behave like children This was well illustrated in the letter from a works manager which appeared lately in our pages (*Lancet*, Oct 18, p 471) three men were asked to do an rescuer of Alexander Selkirk. Then there was Robert Younge, who left a record of the battle of Camperdown in 1797, when his ship H.M.S. *Ardent* lost 41 killed and 107 wounded out of a company of 485, and he was operating for fifteen hours non-stop. Perhaps the most famous of the old naval surgeons was Sir William Beatty, who became friend and surgeon to Nelson, to him we owe an account of those closing scenes on the *Victory*, of Nelson's wounds and end. And he tells how the body was brought home to England steeped in brandy, and of the post-mortem findings. Commander Allison ended his tales of the sea with another quotation from Thomas Trotter:

---

[3] McKissock, W , Wright, J and Miles, A A *Brit med J* Sept 13, 1941, p 375

> “As study and diligence lead to preferment in every department of life, so in our line they have their rewards. We fulfil a most important station in the service of our country, nay of much more importance than we can expect credit for, because many of our best actions must sleep with ourselves, as medical abilities are not to be appreciated by common observers. Yet, this very circumstance is a stimulus to exertion: for it keeps alive the spirit of perseverance, from the hope that merit will at last be discerned and meet with success.”

LOCAL ANÆSTHESIA IN DELIVERY

THE British mind has never accepted local infiltration anæsthesia as the method of choice in pelvic delivery. This reluctance has been explained by several arguments—that most obstetricians prefer a generally anæsthetised patient, since thereby their time is saved and any major procedure required is immediately feasible; that few institutions or chemists can be relied on properly to prepare a reliable local anæsthetic that is safe and certain in its results; that the locally anæsthetised patient requires more supervision than her unconscious sister. But the most likely explanation is that the average practitioner does not understand the local nerve supply of this area of operation since he has never fully studied it from the point of view of infiltrating the nerve paths involved. These arguments, even if valid, are readily overcome. First, as Sheldon[1] insists, it is essential to appreciate the anatomy of the female perineum and genitalia. The nerve supply that must be blocked is a threefold one. The pudic nerve leaves the pelvis through the greater sacrosciatic foramen and joins the pudic vessels in Alcock's canal; it then divides into the perinæal nerve and the dorsal nerve of the clitoris. The inferior hæmorrhoidal nerve branches off the pudic trunk before its terminal division. These nerves traverse the ischiorectal fossa and supply the skin of the perineum, labia minora, a large part of the vagina and part of the labia majora and anus. The second important nerve is the small sciatic; this emerges from the pelvis through the great sacrosciatic foramen and supplies the skin of the perineum and back of the thigh and leg. It gives off the inferior pudendal nerve, which curves forward from below the tuberosity of the ischium to supply the skin of the labia, communicating with the superficial perinæal and inferior hæmorrhoidal branches of the pudic nerve. The third nerve that must be blocked is the ilioinguinal, which emerges from the external abdominal ring to supply the skin of the upper and inner part of the thigh and the skin of the labia. To infiltrate these nerves three points are chosen: the first over the external abdominal ring, the second just medial to the tuberosity of the ischium, and the third in the middle of the perinæal body. From these points a fan-shaped area is infiltrated spreading towards the vagina. About 10 c.cm. of 1% procaine is used for each point, amounting to 50–70 c.cm. in all. Ideally the procaine solution should be freshly prepared and sterilised by autoclaving at 5 lb. pressure for five minutes; it should be made with sterile normal saline. The addition of 10 minims of 1 in 1000 adrenaline to every 100 c.cm. of solution prolongs the anæsthetic effect and has a small but valuable local hæmostatic action. An ordinary Record syringe and a long fine needle are the only other essentials. To get the best results the timing of the injection is important. The first stage is conducted along the usual lines using Omnopon and scopolamine or gas-and-air analgesia. In a primipara the time for infiltration is when the baby's head is on the pelvic floor, but in a multipara as soon as the os is fully dilated. The period of anæsthesia to be expected varies from 1 to 2 hours, and this should suffice in all normal cases. The extent of the anæsthesia is sufficient for the performance of an episiotomy or for the application of the low forceps and the suturing of perinæal tears. There are certain practical considerations that recommend the method. The patient being conscious can be enlisted to coöperate in bearing down efforts as required. She avoids the risk of an inhalation anæsthesia, while the operator has all the muscular relaxation of the outlet such as only a deep general anæsthetic could otherwise provide, thus minimising the likelihood of forceps delivery, episiotomy and laceration. Shock and blood loss are minimal since the uterine tone is not in any way prejudiced by the atonic effects of a general anæsthetic and the chances of an atonic postpartum hæmorrhage are avoided. The benefits to the baby are self-evident; the baby is no more affected than if the delivery had been conducted without any anæsthetic at all and no respiratory depression from inhalation anæsthesia is seen, with a resulting minimum of cases of asphyxia. Sheldon has used this method in 64 cases and finds it eminently satisfactory. It fulfils the ideals of any anæsthetic to be used in obstetrics and its safety for both mother and baby recommend its wider trial.

STUDENT AND SCREEN

THE sound film “Malaria” was shown on Oct. 30 by the Ross Institute of the London School of Hygiene and Tropical Medicine. This film, made by the Shell Film Unit in collaboration with the institute, and produced by Arthur Elton and Graham Tharp, is a beautiful piece of work. The immense problem of malaria is stated, the life history of the parasite is exposed, and finally the watcher is shown how this knowledge can be used as a rational basis for a campaign of preventive medicine on a wide scale. The photography is arresting. Different places where mosquitoes breed are shown as in a travel film; diagrams by Francis Rodker are particularly clear, and the complicated life-cycle of the parasite is demonstrated by excellent microphotographs, the work of Percy Smith and Sidney Beadle.

Such a brilliant presentment of technical material demonstrates the use which could and should be made of the cinema in medical education. Although there are now quite a number of scientific films, most have a limited audience and few are shown to students. In the days before printing, education depended on lectures and readings from rare manuscript books. Printing gave every student access to textbooks and saved him the labour of copying. Lectures continued, nevertheless, to be the basis of education, and attendance at them is still compulsory in some universities, though it would be equally logical to compel the student to read Professor X's book before being allowed to sit for an exam. As the technique of illustrating was perfected, photographs began to invade the pages of the textbooks and the student's eye could feast on static delineations of cells, tissues and organs which in life are never at rest. The cinema film, the ultra rapid camera and the microscope can be used to convey clearly to every member of an audience the details of almost any biological process; yet academic circles in England have hardly noticed this new weapon. The sound film can combine the best, and most carefully prepared, lecture with the exact demonstration of phenomena. Colour, magnification, speeding up or slowing down, can be used to reveal inaccessible processes larger than life and twice as natural it is unlikely to be absorbed readily on account of the grave condition of the patient. Such cases are usually due to a malignant tertian infection, where speed in diagnosis and treatment is essential to lessen the risk of an early fatal issue.

WHEN TO TIE THE CORD

UP to a few years ago there was no difference of opinion about when the umbilical cord should be obliterated and the vascular connexion between mother and infant severed. The standard textbooks usually said "when the cord has ceased pulsating," and this was an easy rule to follow. The first element of doubt crept in as BARCROFT began to publish the results of his fascinating studies on the respiration of the fœtus and newborn baby. It seemed to be a legitimate practical deduction that once the infant's head was clear of the vulva and the respiratory tract was wiped clean of mucus in its upper reaches the sooner the cord was clamped the better, since this ensured the cutting off of oxygen which BARCROFT had shown was the most important stimulus for the first inspiration. So some obstetricians and their pædiatric associates began to urge that the cord should be clamped earlier than hitherto, the pædiatricians adding that since the infant spent the early days of life getting rid of his fœtal polycythæmia there was no harm in preventing the placental apparatus passing over the last few teaspoonfuls of blood. One pædiatrician, asserting that too much blood in the veins (hyperphlebæmia) was the cause of many troubles in infancy and childhood, urged that after the cord was cut some bleeding from the infant's end should be encouraged.

Now certain workers in Chicago are claiming that deprivation of placental blood may be a cause of iron deficiency in infants. According to E. E. WILSON, W. F. WINDLE and H. L. ALT,[1] when the umbilical cord is clamped immediately after birth, over 100 c.cm. of blood can usually be obtained from its placental end. They argue that this is equivalent to about a third of the blood-volume of the newborn infant, and that the iron liberated from the blood normally destroyed in the early days of life is stored and used for hæmoglobin formation in later infancy. If this is so the deprivation of a third of the blood-volume at birth may be a serious threat to the composition of the blood in the second half of the first year of life. Arithmetic is then brought in to suggest that deprivation of placental blood means that at 6 months of age the infant's quantum of hæmoglobin will be 9·1 g. instead of 12 g. per 100 c.cm. and at 9 months of age 9·7 g. instead of 12 g. per 100 c.cm. In order to test the validity of this theory studies were made in a series of infants aged 8–10 months. In 15 of these infants the cord had been clamped immediately after birth and in 13 clamping had been delayed "until the placenta had begun to descend into the vagina." For the former group the average blood values were: red corpuscles 5,060,000 per c.mm., hæmoglobin 10·8 g. per 100 c.cm. and mean corpuscular hæmoglobin 21·8 $\mu\mu g$. For the second group the corresponding figures were 4,450,000 per c.mm., 11·9 g. per 100 c.cm. and 27 $\mu\mu g$. It is claimed that, although the differences in the average erythrocyte counts and hæmoglobin values for the two groups are not highly significant in themselves, the difference between the mean corpuscular hæmoglobin in the two groups is statistically significant and it is considered that the infants in the "immediate clamping" group showed evidence of a mild iron deficiency anæmia.

All the infants investigated, however, came from families of a low income group and although nearly all were receiving some carrots, spinach and other green vegetables it would not be unreasonable to suppose that additional iron, as advocated by some experts for all infants, would readily abolish the slight difference between the two groups. As regards a possible anæmia in later infancy the idea of leaving the cord until the placenta has begun to descend into the vagina cannot then be said to be strongly supported. What may be called the Barcroft point of view seems to have better claims. Further work is still needed to decide whether any change is necessary in the standard midwifery teaching of tying the cord as soon as pulsation ceases.

Annotations

SALT WATER SURGEONS

How old is the profession of ship's doctor? Perhaps as old as the ark, if Shem, Ham and Japheth founded that precedent by which three sons distribute themselves between the church, the law and medicine. But striding down a century or two we find the calling well established in the days of Augustus Cæsar; and Surgeon Commander R. S. Allison, at the opening of the winter session of the Royal Victoria Hospital, Belfast, suggested that St. Luke himself may have been a ship's doctor. In English ships the surgeon had a precarious status, but by the reign of Henry VIII—a monarch justly celebrated for uniting surgeons and barbers—they were doing rather well, the "chief sirurgyon" getting a salary of *13s. 4d.* a month. Queen Elizabeth chose William Gilbert, one of her own physicians and president of the College, to help to stem the increase of disease in her navy; and John Woodall, first surgeon general to East India Company, followed "Generall" Lancaster in recommending lemon juice as a cure for scurvy 180 years before its use became general. Woodall also wrote a textbook for ship's surgeons which became a classic, noteworthy no less for its therapy than its piety. In the seventeenth and eighteenth centuries the status of ship's surgeons was still in the balance. They were not commissioned officers and their pay and quarters were equally poor. *Many of* them were keen and devoted, striving against disease in their ships' companies. Commander Allison recalled Smollett's grim account (in "Roderick Random") of his experiences, and quoted the vivid picture drawn by William Cockburn in 1697 of the ravages of typhus. He also mentioned Richard Walter, who described how severe scurvy could dissolve the callus of a well healed fracture and leave it disunited; and Lind and Anson, who found that "the number of seamen in time of war, who die of shipwreck, capture, famine, fire and sword are inconsiderable in respect of such as are destroyed by the sea diseases." Another eighteenth century sea surgeon, Thomas Trotter, fought well for his sailors, demanding from the Lords of the Admiralty not only the fresh fruits and vegetables which would clear their fleets of scurvy but other amenities. "Give your tars," said he, "Oh my countrymen, their amusements; and while you enjoy yours on shore remember who they are that gave you security." And how strange that Dover's powder—that symbol of drowsiness and gentle perspiration—should be the nostrum of a pirate who was presumably his own ship's doctor. Thomas Dover, physician and privateer, the scuer of Alexander Selkirk Then there was Robert ounge, who left a record of the battle of Camperdown 1797, when his ship H M S *Ardent* lost 41 killed and 7 wounded out of a company of 485, and he was erating for fifteen hours non-stop Perhaps the most mous of the old naval surgeons was Sir William Beatty, ho became friend and surgeon to Nelson , to him we ve an account of those closing scenes on the *Victory*, Nelson's wounds and end And he tells how the body as brought home to England steeped in brandy, and of he post-mortem findings Commander Allison ended is tales of the sea with another quotation from Thomas rotter

> "As study and diligence lead to preferment in every epartment of life, so in our line they have their rewards Ve fulfil a *most important station in the service* of our ountry , nay of much more importance than we can expect redit for, because many of our best actions must sleep with urselves, as medical abilities are not to be appreciated by ommon observers Yet, this very circumstance is a stimulus o exertion for it keeps alive the spirit of perseverance, rom the hope that merit will at last be discerned and meet vith success"

LOCAL ANÆSTHESIA IN DELIVERY

THE British mind has never accepted local infiltration anæsthesia as the method of choice in pelvic delivery This reluctance has been explained by several arguments —that most obstetricians prefer a generally anæsthetised patient, since thereby their time is saved and any major procedure required is immediately feasible , that few institutions or chemists can be relied on properly to prepare a reliable local anæsthetic that is safe and certain in its results , that the locally anæsthetised patient requires more supervision than her unconscious sister But the most likely explanation is that the average practitioner does not understand the local nerve-supply of this area of operation since he has never fully studied it from the point of view of infiltrating the nerve paths involved These arguments, even if valid, are readily overcome First, as Sheldon[1] insists, it is essential to appreciate the anatomy of the female perinæum and genitalia The nerve-supply that must be blocked is a threefold one The pudic nerve leaves the pelvis through the greater sacrosciatic foramen and joins the pudic vessels in Alcock's canal , it then divides into the perinæal nerve and the dorsal nerve of the clitoris The inferior hæmorrhoidal nerve branches off the pudic trunk before its terminal division These nerves traverse the ischiorectal fossa and supply the skin of the perinæum, labia minora, a large part of the vagina and part of the labia majora and anus The second important nerve is the small sciatic , this emerges from the pelvis through the great sacrosciatic foramen and supplies the skin of the perinæum and back of the thigh and leg It gives off the inferior pudendal nerve, which curves forward from below the tuberosity of the ischium to supply the skin of the labia, communicating with the superficial perinæal and inferior hæmorrhoidal branches of the pudic nerve The third nerve that must be blocked is the ilioinguinal, which emerges from the external abdominal ring to supply the skin of the upper and inner part of the thigh and the skin of the labia To infiltrate these nerves three points are chosen the first over the external abdominal ring, the second just medial to the tuberosity of the ischium, and the third in the middle of the perinæal body From these points a fan-shaped area is infiltrated spreading towards the vagina About 10 c cm of 1% procaine is used for each point, amounting to 50–70 c cm in all Ideally the procaine solution should be freshly prepared and sterilised by autoclaving at 5 lb pressure for five minutes , it should be made with sterile normal saline The addition of 10 minims of 1 in 1000 adrenaline to every 100 c cm of solution prolongs the anæsthetic effect and has a small but valuable local hæmostatic action An ordinary Record syringe and a long fine needle are the only other essentials To get the best results the timing of the injection is important The first stage is conducted along the usual lines using Omnopon and scopolamine or gas-and-air analgesia In a primipara the time for infiltration is when the baby's head is on the pelvic floor, but in a multipara as soon as the os is fully dilated. The period of anæsthesia to be expected varies from 1 to 2 hours, and this should suffice in all normal cases The extent of the anæsthesia is sufficient for the performance of an episiotomy or for the application of the low forceps and the suturing of perinæal tears There are certain practical considerations that recommend the method The patient being conscious can be enlisted to coöperate in bearing down efforts as required She avoids the risk of an inhalation anæsthesia, while the operator has all the muscular relaxation of the outlet such as only a deep general anæsthetic could otherwise provide, thus minimising the likelihood of forceps delivery, episiotomy and laceration Shock and blood loss are minimal since the uterine tone is not in any way prejudiced by the atonic effects of a general anæsthetic and the chances of an atonic *postpartum* hæmorrhage are avoided The benefits to the baby are self-evident , the baby is no more affected than if the delivery had been conducted without any anæsthetic at all and no respiratory depression from inhalation anæsthesia is seen, with a resulting minimum of cases of asphyxia Sheldon has used this method in 64 cases and finds it eminently satisfactory It fulfils the ideals of any anæsthetic to be used in obstetrics and its safety for both mother and baby recommend its wider trial

STUDENT AND SCREEN

THE sound film "Malaria" was shown on Oct 30 by the Ross Institute of the London School of Hygiene and Tropical Medicine This film made by the Shell Film Unit in collaboration with the institute, and produced by Arthur Elton and Graham Tharp, is a beautiful piece of work The immense problem of malaria is stated, the life history of the parasite is exposed, and finally the watcher is shown how this knowledge can be used as a rational basis for a campaign of preventive medicine on a wide scale The photography is arresting Different places where mosquitoes breed are shown as in a travel film , diagrams by Francis Rodker are particularly clear, and the complicated life-cycle of the parasite is demonstrated by excellent microphotographs, the work of Percy Smith and Sidney Beadle

Such a brilliant presentment of technical material demonstrates the use which could and should be made of the cinema in medical education Although there are now quite a number of scientific films, most have a limited audience and few are shown to students In the days before printing, education depended on lectures and readings from rare manuscript books Printing gave every student access to textbooks and saved him the labour of copying Lectures continued, nevertheless, to be the basis of education, and attendance at them is still compulsory in some universities, though it would be equally logical to compel the student to read Professor X's book before being allowed to sit for an exam As the technique of illustrating was perfected, photographs began to invade the pages of the textbooks and the student's eye could feast on static delineations of cells, tissues and organs which in life are never at rest The cinema film, the ultra-rapid camera and the microscope can be used to convey clearly to every member of an audience the details of almost any biological process , yet academic circles in England have hardly noticed this new weapon The sound film can combine the best, and most carefully prepared, lecture with the exact demonstration of phenomena Colour, magnification, speeding up or slowing down, can be used to reveal inaccessible processes larger than life and twice as natural

Even the work-shy student, with ears like the deaf adder's for the lecturer's drone and eyes revolted by the sight of type, might be stimulated by cinematic tuition Young men and maidens have been known to cut lectures, they seldom miss the flicks

The movie has one priceless perquisite Time is no object a thousand years is as a day, and a day as a thousand years, just a function of the speed of the clockwork Fifty years ago Muybridge's slow-motion pictures taught us how we run and jump, the name of Canti stands for the quick-motion solution of the solemn process of tissue culture The film is not just an adjuvant to the news story, it is the only way of bringing home the rhythm of life

THE BOOKS GO ROUND

THE International Guild of Hospital Librarians is not to be put off by a mere blitz Some hospitals have lost the better part of their libraries along with much else, others have been more fortunate *Book Trolley* for October tells of volumes repaired, librarians appointed, patients giving a capable hand, and service steadily maintained There are stories of resource, too—of the librarian who met the needs of two Polish airmen with seven Polish books and a dictionary, and trained a one-author man (the author was Nat Gould) to nibble at Zane Grey and then by gradual degrees to swallow most of John Buchan and a stiff dose of Cronin This reading habit grows on us with war

Nor are the troops forgotten The Red Cross and St John Hospital Library has been developing into a vigorous and widespread service since the war began Bales of books are being sent out regularly to the depots and hospitals in the Middle East, Kenya, Iraq, Iceland, West Africa and Gibraltar, as well as the sick quarters of the Navy and R A F During the summer books and magazines have been sent out at home and abroad at the rate of more than twenty thousand a month The books which come in from donors have to be sifted, for many people anxious to be of service have sent along all manner of books, regardless of aptness for the purpose Thus "A Treatise on Elephants" has been known to arrive cheek by jowl with "Better Bed Manners" At home war has made for useful decentralisation, book depots have been established in every county of England and Wales and in many provincial cities They collect and distribute, sort and mend books Voluntary librarians sometimes helped by professionals have been appointed who have been able to meet the needs of patients methodically, thanks to the experience gained in the library service during the past twenty years

TUBERCULOSIS IN DUBLIN CHILDREN

THE tuberculosis mortality of the child population of Dublin City for the years 1930–36 was 8 per 10,000 children in the age-groups 0–15, and for 1937–39, 7 per 10,000 These figures led the Irish Pædiatric Association to make a tuberculin survey in the hospitals of the city and a report compiled by Dr Dorothy Price has now been issued[1] Six hospitals participated in the survey, and the tuberculin test employed throughout the investigation was the Hamburger percutaneous ointment The association are well satisfied with this as an initial test, finding it reliable, simple and painless A group of 1121 children were tested in the age-groups 0–14, of whom 230 reacted The reactors at all ages were thus 20 5% of the total tested, the percentage increasing from 4 6 in the 0–1 year group to 46 1 in the 10–14 year group Sex-incidence showed a slight preponderance of female positive reactors (4%) No less than 22 unsuspected cases of active tuberculosis were diagnosed by means of the test The radiological findings in 116 of the children with positive reactions showed that 67 were suffering from active lesions which required treatment, 6 died Physical examination of the lungs gave very misleading results, primary pulmonary infection could not be diagnosed by stethoscopy, and tuberculous could not be distinguished from non-tuberculous pneumonia As a general rule a high erythrocyte sedimentation rate was found to indicate an exudative lesion, whereas a low one pointed either to a healing lesion or to a caseous or advanced tuberculous focus with bad prognosis An analysis of the source of infection in 38 cases, most of them under 5, showed that the father was the source of infection in 12 and the mother in 9 In attempting to correlate the housing conditions with the incidence of tuberculosis it was noted that the tuberculinisation of the childhood community appeared to be evenly distributed among all classes of dwelling, but that the slum child had much greater difficulty in healing his tuberculous lesion The word "slum" is used in the report to indicate "one room in a tenement house, basement, or dilapidated cottage" The report tabulates a number of possible measures for meeting the situation Excluding as impracticable the removal of a child exposed to infection under some sort of Grancher system, or the removal of the infecting adult by compulsory segregation, Dr Price considers that the best method of prevention is early diagnosis, combined with prophylactic vaccination, increased institutional accommodation, and educational propaganda

PNEUMOCOCCAL MENINGITIS

ALTHOUGH pneumococcal meningitis is comparatively rare—only 7% of Neal's[1] 3131 collected cases of acute and chronic meningitis were pneumococcal—it was until the introduction of the sulphonamides almost invariably fatal Perhaps more often secondary than primary, with otitis media and pneumonia the commonest primary infections, pneumococcal meningitis affects young children and elderly people more than it does other age-groups, having in this respect some resemblance to bronchopneumonia While any one of the 30 odd pneumococcus types may be the infecting agent, type III pneumococcus is the most common single type in this infection and is particularly associated with meningitis in older patients as a sequel to an insidious otitis media or mastoiditis Since sulphanilamide is effective against this type, determination of the pneumococcus type in meningitis is probably always worth while, for some patients do not easily tolerate sulphapyridine Indeed the good results obtained with sulphanilamide in the treatment of pneumococcal meningitis (including types other than type III) have prompted Steele and Gottlieb[2] in a recent review to rank it alongside sulphapyridine, which besides being more toxic is less uniformly absorbed Howard[3] in his report of the recovery of a child aged 1 year—a very rare occurrence at this age even in these sulphonamide days—suggests that sulphathiazole is the drug of choice If so it must be given at regular four-hourly intervals for its rapid excretion makes a constant concentration in the tissues difficult to maintain No one will now deny that all three of these sulphonamides can miraculously save patients with pneumococcal meningitis, but it is not easy to say what proportion of treated cases do actually recover, for it is inevitable that successes will be published more often than failures, and an analysis of the published cases is not a fair criterion of the case fatality under sulphonamide therapy This point is exemplified in the series of 14 cases with only one recovery recorded by Cooke[4] It will be noted that of his fourteen cases nine were over 45 years of age and two under 2 years which from the prognostic viewpoint are the unfavourable age groups with sulphonamide therapy the recovered patient was aged 22 Apart from age, probably the most important

[4] Cooke, W T *Ibid* p 510

factor in recovery is early institution of chemotherapy The drug should be given at the first suggestion of meningeal symptoms even though this means treating cases of meningismus, and the initial doses should be large enough to ensure an adequate concentration as early as possible , Steele and Gottlieb suggest a cerebrospinal fluid level of 10 mg per 100 c cm for sulphanilamide and 5 mg per 100 c cm for sulphapyridine Improvement should be evident within 2–3 days, but the drug should not be discontinued too soon, lest there be a relapse of the infection As always with sulphapyridine or sulphathiazole, as much fluid as possible should be given in order to avoid deposition of the drug in the urinary tract Surgical treatment is needed where there is middle ear or mastoid disease, and these cases usually do well Opinion is divided on the need for or value of adjuvant serum-treatment, but there is no conclusive evidence that it contributes to recovery

ESTIMATION OF SULPHONAMIDES IN THE BLOOD

IT is neither necessary nor practicable to estimate the amount of sulphanilamide or its derivatives in the blood of every patient receiving one of these drugs Apart from research there are occasions when the determination is helpful—for example, in the treatment of pneumococcal meningitis or to make sure that the drug is being adequately absorbed when an infection fails to respond to treatment Various methods have been elaborated for the determination , they usually depend on preliminary diazotisation of the sulphonamide followed by conjugation with an aromatic amine Sheftel[1] has described a bedside micro modification of Marshall's method Conjugation is effected with N(1-naphthyl) ethylenediamine dihydrochloride, all the reagents being added in the form of tablets to the blood diluted with water the final colour being compared with a lucite wedge in a special colorimeter Sheftel uses the same wedge for estimating sulphanilamide, sulphapyridine and sulphathiazole and does not mention the difficulties of comparison due to differences in the colours given by the three compounds As a bedside method the results should be adequate and the principal objection to the method seems to be the necessity for a special colorimeter Scott[2] discusses a simplification of the macroscopic laboratory methods which employ dimethyl-α-naphthylamine His method as applied to blood-plasma should avoid the errors arising from adsorption of sulphonamide on the protein, an error which various observers have shown to amount to 5 or 10% Scott describes the application of the method to whole blood, and while this is less satisfactory there are occasions when, because of hæmolysis or because only a small amount of blood can be obtained, plasma cannot be used

CUCUMBER SEEDS AND CLINICAL MEDICINE

A MATERIAL advance in knowledge often follows an improvement in the technique of assay But some of the newer methods involve the use of biological reagents which seem, to those not hardened to it by experience, to be bizarre and much too fantastic to be of use to ordinary men Some of the more exotic methods for the biological assay of the sex hormones may be recalled in this connexion It may even seem rather a far cry to many clinicians from cucumber seeds to scurvy, but, nevertheless, there is a connexion, and it is really a simple and logical one Cucumber seeds contain a very active enzyme which oxidises ascorbic acid Meiklejohn and Stewart[3] have taken advantage of this fact to elaborate what promises to be an elegant method for the determination of the antiscorbutic vitamin The principle may be compared with the one, more familiar to medical men, of using an enzyme from the Jack, or Soya bean, to determine the amount of urea in blood or urine The great advantage of Meiklejohn and Stewart's method over the older ones for estimating the amount of ascorbic acid in, let us say, urine, is the specificity which it introduces into the assay Nothing but ascorbic acid will react, which is far from being the case with the older methods As described, the method is naturally a little more complicated than the older ones, but it involves no elaborate apparatus and its manipulation ought to be relatively simple Incidentally, in the course of their research, Meiklejohn and Stewart have made a pretty little contribution to pure science, by showing that the enzyme which oxidises ascorbic acid is a copper protein compound It must give them considerable intellectual satisfaction, in these days of death, to think that they have been instrumental in discovering one of the biological functions of copper, and demonstrating one of the reasons why minute quantities of it seem to be essential to life

TUBERCULOUS RHEUMATISM

THE forty years that have elapsed since Poncet[1] introduced the concept of " tuberculous toxic polyarthritis " have seen much argument as to whether the syndrome exists, but relatively little fact that was either relevant to the issue or incontrovertible The extensive review covering 240 references by Brav and Hench[2] in 1934 concluded that evidence on which to base the concept was lacking Copeman[3] in this country was able to find only 12 case-records in the literature , typical tubercles were found in one out of four biopsies Proof that the syndrome is distinct both from rheumatoid arthritis in a patient with tuberculosis and from tuberculosis affecting several joints (which [illegible] occasionally does) must depend on the demonstration of a histological appearance differing from either Kling and Levine[4] have now published a full and carefully documented account of one such supposed case, with a previous history of " open " tuberculosis, an arthritis thought to be of rheumatoid type in the left knee, and fleeting pains in various other joints European observers diagnosed Poncet-type rheumatism A synovectomy revealed, histologically, fibrotic tubercles and caseation with a few acid-fast bacilli, a positive culture and positive animal inoculation The conclusion reached is that a mild type of tuberculous polyarthritis does occur, due to hæmatogenous infection from a visceral focus associated with high tissue resistance The use of Poncet's term " rhumatisme tuberculeux " should be avoided, for it leads only to confusion , the diagnosis made should be either " rheumatoid arthritis " or " non-destructive tuberculous arthritis " In this country we seldom diagnose " tuberculous rheumatism," but it seems possible that some cases of this nature are masquerading as " atypical, or monarticular, rheumatoid arthritis " to the detriment of the patient and the public The failure of aspiration to give confirmation in proved cases of tuberculous arthritis points to biopsy as the only certain and incontrovertible proof This should, in selected cases, be more often practised

---

Surgeon Rear-Admiral G GORDON-TAYLOR F R C S , has arrived in Boston to attend the clinical congress of the American College of Surgeons as a representative of the Royal Navy and the Royal College of Surgeons of England

The Minister of Health has asked that tuberculosis notifications from county councils, county borough councils, urban and rural district councils and joint tuberculosis boards shall reach his department not later than six days after the end of the four-weekly periods to which the returns relate

JUVENILE DELINQUENCY IN WAR-TIME

REPORT FROM THE BRISTOL CHILD-GUIDANCE CLINIC

F H BODMAN, M D BRIST
ACTING DIRECTOR, BRISTOL CHILD GUIDANCE CLINIC

M I DUNSDON, M A
PSYCHOLOGIST TO THE BRISTOL EDUCATION COMMITTEE

AN analysis has been made of the cases referred by magistrates and probation officers to the Bristol child-guidance clinic during the past two years These cases constitute approximately a third of all the children actually charged, and these delinquents in their turn represent only a small proportion of the socially unsatisfactory and incompetent group in the population It is however a significant proportion, since it is obviously constituted by those whose degree of incompetence is sufficiently serious to prevent their making a satisfactory social adjustment without some special provision for training

The period April, 1939–40, can be taken as an example of a peace-time era, because the war, as far as this country was concerned, was then in a latent state The period April, 1940–41, can be considered representative of a war year Restrictions had been increased, bombing had begun in June and the war had involved in some way practically every family in Bristol

CASES REFERRED TO THE CLINIC

The number of juvenile offenders who were charged and referred by magistrates and probation officers to the clinic was 68 in 1939–40, and 100 in 1910–41 These children have been classified into groups according to their intelligence (see table)

Group	IQ	1939–40	1940–41
		Per cent	
Normal	86 and over	69	46
Very dull	70–85	7 4	31
High grade feeble minded	55–70	22 1	21
Certifiable mental defective	under 55	1 5	2
Total subnormal	under 85	31	54

An analysis of the war-year cases shows not only a heavy incidence of recidivism (39%) but also an additional and almost equally large group of children (30%) who had committed previous offences—in some cases as many as 11—for which no charge had been preferred Though technically first offenders, they were in actual fact far from so being Thus, in all, 69% had committed previous offences

A further analysis of the recidivist figures brought out the serious problem presented by the very dull section (intelligence quotient 70–85) Intelligence distribution among 39 children previously charged was as follows

I Q under 70	8 (21%)	86–100	9 (23%)
70–85	19 (49%)	Over 100	3 (7%)

The importance in social adjustment of a normal home background with adequate and consistent domestic discipline, and the unsatisfactory state of affairs which results when these factors are missing is indicated by the following figures

	Per cent
Parents divorced, separated or deserted	15
One parent dead, away from home for long periods, or both parents working	15
Other domestic factors	22
Total	52

Out of this 52% it will be seen that in at least 30% a “ broken home ” was a contributory factor

Parallel with these analyses, an assessment was made of the children who were seriously backward in their school work, even when full allowance had been made for their limited mental capacity, 63% fell in this group in 1939–40, and 47% in 1940–41 In both years, twice as many offences were committed in the half year October to April as in the April to October half Among the mentally subnormal groups, however, the numbers in the winter were twice those of the summer months in the peace year, and had risen in the war year to three times those of the summer months

DISTRIBUTION OF THE INCREASE

There has been a 47% general increase in the numbers referred from the juvenile courts in the war period 1940–41 compared with 1939–40 Among the mentally subnormal groups, the increase has been a disproportionately greater one of 74%

Normal children —It is encouraging to notice that among children of normal mentality there have been considerably fewer charges during the war period Whether the decrease of 23% indicates actually fewer offences in this group, or whether the apparent decline is merely the result of more opportunities of committing offences with less chance of discovery, is impossible to discuss from these figures There are, however, justifiable grounds for believing that the more intelligent children are more readily able to find substitute occupations and recreations when their normal outlets are closed or reduced by war-time conditions When fathers are in the Forces or mothers are at work, many of these children now assume greater responsibilities and tend to take a larger share in the organisation of the home and in consequence have less time on their hands for possible mischief

Very dull children —The main rise in numbers has been in the group of children classified as very dull In this group (I Q 70–85) the numbers have risen sixfold and they now account for nearly a third of the total cases These children at 14 have mental ages ranging from 9½ to 11½ years They have little foresight and are unable to work out in advance the consequence of their actions Their memories are poor so that they learn very slowly from experience Being less critical, they are more suggestible and easily led astray With these handicaps they require more supervision than children of normal intelligence and though not actually defective they are often mentally inefficient Under war conditions they are receiving not more but less supervision In many cases the father has left home for the Forces, or is less often at home, either working on *night shift* or overtime in armaments factories, or is in one of the civil defence services In some cases, the mother also has less time in the home than formerly, she is either working on munitions or in the defence services, or is in some other way attempting to supplement the family income to meet rising costs

Added to the decrease in parental supervision, there is also the effect of the disorganisation necessarily brought about in the schools by damage, evacuation of personnel, altered hours of work and disturbed nights School attendance officers are heavily overworked Yet they often have to waste valuable time in abortive efforts to make contact with the parents of children who for no other reason than lack of supervision are failing to attend school These seriously dull children have more drive than those in the more defective groups, but their drive is often uncontrolled and misdirected It is not surprising that the main increase in juvenile delinquency comes from this group

High-grade feeble-minded children —These children at 14 have mental capacities equivalent to children of 7½–9½ years They are certifiable under the Education Act 1921, but not under the Mental Deficiency Act 1927 In this group (I Q 55–70) the actual numbers during the war year rose by 40%, though the proportional incidence remained constant at about 21%, or a fifth of all cases This percentage is alarming, since the proportion of people normally found to fall in this group from a cross-section of the whole population is only 1 5–2% These children are not suitable candidates for institutions or colonies for the lower grades of defect With suitable training they should become economically independent adults , from their ranks are drawn a large proportion of the casual labourers and unskilled artisans essentia to industry and the maintenance of the public services On the other hand, they are unlikely to benefit from residence in a Home Office approved school They find difficulty in grasping the relation between cause and effect, and with the handicap of a poor memory they lack common foresight and cannot readily learn from previous experience They do not give satisfaction on probation, for though they are often suggestible and readily give promises they are incapable of keeping these promises of better behaviour without consistent supervision, and seldom see any connexion between their actions and the consequences There is thus no satisfactory provision for them and they remain a dangerously weak link in the social structure

Certifiable defectives—The last and smallest group to which attention is drawn is that of defectives certifiable under the Mental Deficiency Act 1927

These children (I Q under 55) at 14 have a mental age below that of an average child of 7½ years The actual percentage of these sent by the juvenile court to the clinic remained the same in the war year as in the previous year (about 2% of all cases) although twice as many of these children were actually referred Very few of these defectives have sufficient initiative to get into serious trouble, and such cases as pass through the courts have as a rule been exploited by people with relatively higher intelligence It should be noted that of 40 children belonging to the last two groups of defectives referred from the juvenile court, only one had attended a special school, the other 39 had attended an ordinary elementary school Incidentally, in a period earlier than the two years under discussion, out of 70 juvenile-court cases who were defectives only one had been to a special school It does not require much imagination to envisage the wastage which this state of affairs involves in the efforts of the school staffs, in the slowing down of the education of the more normal children, and in the apathy induced in these defective children by failure to keep up with the normal curriculum

The extent of recidivism, particularly among the more seriously dull groups, points clearly to the present lack of appropriate provision for dealing with those who are mentally incapable of profiting from warnings and who do not understand the meaning of probation as a period in which to prove their ability and their intention to keep out of future trouble Their attitude in fact is rather that probation offers a "soft option" and they feel that they have justifiable cause for resentment and complaint if probation is not renewed on the occasion of further charges In the borderline groups (I Q under 85) it is hardly surprising that they should take this view since, when approved schools are unwilling to accept them, there is no other course open to the magistrates That birching has not the deterrent effect in these dull children commonly attributed to it has been proved over and over again by the number of cases in which such punishment has been carried out as often as four or five times in as many weeks, without any improvement in the attitude of those who have received it

HOME AND EDUCATION

Present abnormal conditions are revealing more clearly than ever the importance of consistent home discipline and normal family life as major factors in social adjustment Juvenile court cases for the past year provide evidence for study of the factors which are hampering preventive measures Economic deprivation in itself is not so great an aggravating factor in the increase in juvenile delinquency as the lack of consistent parental control Occasional sporadic attempts at severe punishment for misdemeanours which are as frequently condoned or allowed to pass unchecked results in an equally unreliable attitude on the part of the child, especially when the parents' attitude swings unaccountably from injudicious harshness to foolish leniency Many parents in court, fearing that they will be censured, attempt to give a misleading impression of having exerted a satisfactory degree of control, but directly they feel that the immediate crisis has passed relapse into their favourite attitude of laissez-faire Such parents cannot be relied on to coöperate satisfactorily in probation It is significant that in more than half the cases charged during the past year there was evidence of lack of normal home discipline Present social conditions are undoubtedly contributing to an increased number of homes where parents are absent for long periods, or where owing to the demands of night work they must sleep during the daytime and so cannot give normal supervision Lack of control cannot be attributed to war conditions alone In 15% of cases there was a history of unsatisfactory matrimonial situations, while in a further 22% none of these factors was present and lack of control was mainly due to poor intelligence or ineffectual handling on the part of both parents

Backwardness in school work was further investigated among the juvenile delinquents and a very high proportion of educationally retarded children was found These children had failed to reach their possible level, even when full allowance was made for their intellectual defects Among juvenile delinquents of school age, there has been a rise of 6% in those children who are failing to make the progress of which they are mentally capable This figure does not include those dull and defective children who are working up to their limited capacities These educationally backward children are acquiring or have already acquired a habit of failure, they are beginning to drift and will continue to do so when they leave school Of children of employable age, we found 60% seriously educationally retarded in the fundamental subjects This figure for Bristol delinquents closely corresponds to the percentage of children found to be seriously educationally retarded among 4000 juvenile delinquents examined in the London metropolitan area a few years ago

The long blackout hours in winter involve restrictions of many possible outlets which are available in the long summer evenings These restrictions are felt to some extent by everyone, but whereas people of normal abilities are able to find recreation in reading or in constructive occupations and hobbies those children who lack both interest and skill in such pastimes spend their leisure time in aimless wandering and street gang play and do not easily discover substitute occupations Such children are only too ready to take advantage of the opportunities to enter damaged buildings, and to tamper with the easily accessible A R P equipment in public shelters, without either realising or considering the possibility that their actions may involve other people's safety or property Many of them come from housing estates of the slum-clearance type Geographically healthy these estates are too large to have any sort of social cohesion, while opportunities for corporate life and recreation are fewer than were available in the neighbourhoods from which the families originally were moved

RECOMMENDATIONS

War conditions, including evacuation, necessitate a short-term policy during the war and a long-term policy for peace-time conditions Ascertainment of dull children in the schools should of course be continued and if possible extended At present, there is little or no provision for half the class of children coming before the juvenile court in increasingly large numbers

Very dull children (I Q 70–85) are not certifiable under either act, and neither can nor should be segregated with lower grade defectives (I Q under 55) in colonies On the other hand, they are not welcomed by the headmasters of approved schools, and rightly so, since they cannot benefit from the curriculum of the ordinary approved school At present these cases can only be put on probation, and in spite of the devoted labours of the probation officers it must be acknowledged that results in this group are unsatisfactory Very dull children over school age are found by employers to be poor workmen, and in consequence they are always changing their occupation Parental discipline is often absent, owing to war conditions, and opportunities for adventure are multiplied, particularly in bombed areas Much more supervision than a weekly interview by the probation officer is required in these cases As things are the child comes again and again before the court, and the numbers of such children are far out of proportion to their percentage incidence in the population

A special approved school is needed for these children, with an appropriately adjusted curriculum in which class-work should occupy only part of the time and should be linked with occupational training suitable for their limited capacities and likely to be an important factor in fitting them to live in the general community Eighteen months or two years in such a school would condition these children and provide them with the necessary day to day supervision and discipline which is so badly needed If an effort were made to train them to make full use of their capacities, even if limited, they should be able to take up a suitable occupation on discharge with some hope of permanence

The same remarks apply to high-grade feeble-minded children (I Q 55–70) These are certifiable under the Education Act, and if of school age can be sent to a special school, but they are not certifiable under the Mental Deficiency Act, and are not suitable for segregation in existing colonies, which are intended for those whose social incompetence is of such a degree that they are incapable of attaining economic independence It is even more difficult to find suitable employment for them than for the very dull, and they are extremely difficult to supervise on probation, moreover, their parents are often borderline or actual defectives, and are unable to exercise proper discipline Were there suitable provision in residential special schools for many of this type it is unlikely that anything like the disproportionately large numbers of them now being charged would ever have to appear in court The heavy incidence of delinquency among them is not merely a war effect in more normal times anything from 10 to 15 times as many cases appear to be drawn from this group as should reasonably be expected if they appeared roughly in proportion to their incidence in the general population

Many certifiable defectives (I Q under 55) who come before the courts would never have been charged had they been given the chance of training at a day occupation centre, which if properly organised should fit some for partial self-support and would at least keep others out of mischief Those who in spite of such training, or from lack of suitable home circumstances, were found still to be incapable of social adjustment should, of course, be certified and sent to a colony

Evacuation —Neither the high-grade feeble-minded (I Q 55–70) nor the defectives (I Q under 55) are suitable for evacuation to ordinary billets in reception areas Quite a number, however, have been sent and have given a good deal of trouble to the foster parents and to the authorities in the reception areas Children with I Q under 55 cannot be expected to receive from the ordinary billeting arrangements that training and supervision which colony placement provides They should therefore be certified and sent to such institutes as are provided in comparatively safe districts outside the city Children with I Q 55–70 should normally be certified under the Education Act and sent to a special school, though nothing like full advantage has been taken of the available powers, partly because of the limited accommodation available in Bristol These children, if evacuated, should go en bloc, as a residential school or schools They require special supervision and teaching which cannot be provided in the ordinary billets or in the ordinary rural schools—which, with the advent of evacuees, are usually understaffed

Some of the very dull group (I Q 70–85) would also do better in a residential school or farm institute than in ordinary billets This applies particularly to those who have been in frequent trouble School work would not take up all the syllabus, and a good deal of time could usefully be spent in outdoor work or in an occupational centre which could be easily provided in a farm school

Children remaining at home —In all cases where parental supervision is inadequate and a child is defective within the meaning of the act, he should be sent to a colony outside the target area The high-grade feeble-minded (I Q 55–70) should be drafted into a special school, where there should soon be more places available owing to evacuation It is to be hoped that magistrates and teachers will encourage parents to take advantage of special day-school provision For the group of very dull children (I Q 70–85) who form the “ C ” and “ D ” streams in many schools, it would probably be useful if less class-work and more occupational work could be arranged

For all groups, during the winter, further organisation of leisure is needed to provide outlets for misdirected energies and the desire for adventure normal in the growing boy and girl Much good work has been done on a small scale during the past winter in the social centres which have sprung up all over the city in crypt and basement shelters These provided the atmosphere of a club where neighbours could meet their friends in the evening in safety, and replaced to some extent the usual recreations made impossible by the blackout and A R P More centres might be developed on these lines in places of safety, where parents could send their children, not to sleep but to spend the evening Recreational facilities such as film shows and concerts in these centres might be expanded

Long-term policy should be preventive The present provision for both very dull and defective children is inadequate It is essential that sufficient special school accommodation should be provided after the war for the group of high-grade feeble-minded, and one such school should be residential Early ascertainment and the transfer of children with I Q 55–70 to a special school where the curriculum will be suited to their special requirements, including occupational training, will be desirable if these children are to be brought up as good citizens playing their parts according to their talents If they are to be prevented from drifting into an apathetic state in which they are only conscious of all-round failure, or into a situation where they can evade all training and education because of lack of provision for their needs, it will be necessary to develop what skill they have so that they may take that pride in their work which is necessary to every citizen’s self-respect

We wish to thank Councillor F C Williams, chairman of Bristol education committee, for permission to publish this paper, and Lady Inskip and Dr J F Lyons for their interest

PARALLELS IN NURSING PROBLEMS

AFRICA is in the act of developing a nursing service to meet the special needs of a scattered and superstitious rural community It might seem on the face of it that nursing problems encountered there must differ fundamentally from those which trouble us here, but Dr Janet Welch’s study [1] of nursing education in relation to the cultural background in East and South-East African colonies shows that we can learn from their difficulties, as they can learn from our mistakes Speaking at a meeting of the Overseas Association of the Medical Women’s Federation on Oct 20, Dr Welch said that it would be difficult to set up any systematic form of nursing education in the African colonies until it was clear whether the policy of the medical authorities was going to put emphasis on curative or preventive work She believed that the hospitals must be centres of social teaching and the nurses must be trained as community nurses from the start, with a sound education in the preventive aspects of hygiene, midwifery, maternity and child-welfare work, and nutrition

A BACKGROUND OF WITCHCRAFT

In Africa as here, the standard of education in the nursing candidate is often lower than could be wished But whereas here secondary education is available for all who attain a given standard, in many African districts primary education alone is available Thus at the time of Dr Welch’s survey, Makerere College in Uganda was giving a full secondary education course, and several other schools were giving incomplete courses, in Kenya there were no schools giving a full secondary course but two grant-aided missionary schools offered junior secondary standard, in Tanganyika five schools were giving some secondary education and in Nyasaland and Northern Rhodesia no secondary education was available It is difficult, even in England with a background of Western culture, to imbue some of the girls now enrolling with any precise idea of the principles underlying aseptic technique and barrier nursing With an African girl coming from a home where sickness is automatically attributed to witchcraft, and to whom the idea of bacteria as a cause of disease is completely foreign, the difficulty is formidable If she has reached standard six she may be able to follow simple explanations in English, if not she must be taught in the vernacular Yet these obstacles can be overcome and Dr Welch records how

She introduced a group of African mothers in a village clinic to the conception of bacteria by easy stages, first showing them how spectacles—with which they were familiar—enlarged the size of letters; then letting them magnify common objects with a hand lens, so that they came to realise that invisible things might be enlarged until they became visible. After this the women were introduced to the microscope and quickly learned to see new detail in familiar objects—dust on a hair, dirt on a fly's leg, pollen in a flower. Then followed a discussion of the idea that invisible things might have life—things smaller than a mite—and the women were sent to draw water from the stream which they used for bathing, drinking and washing. "The demonstration of amœbæ and other microscopic water life in what appeared to them as clear water astounds them, but convinces them of the world of micro-organisms in a way that weeks of verbal description would not." It is easy to make the final step and persuade them that some living organisms are the cause of disease if they enter the body.

This "laboratory approach" would make it possible to teach the nurse the principles underlying her training, and also to introduce the preventive aspects of her work from the start.

GIVE ME THE FIRST YEAR AND ——

Many of the African girls marry and leave the nursing school within a year of entering. During their first year they are used largely as unskilled labour to run the hospitals, and there is little attempt to equip them as future educators of their people. Dr Welch believes that the first year of training can be so planned that it is a unit in itself, providing the nurse with standards and principles for the prevention of disease. Thus, however short her training, she would return to her home fit to teach her friends something better and to establish new ideas of hygiene, nutrition and the care of the child. This is especially important in Africa because the women control the acceptance of new ideas. Many of the tribes were originally matrilinear in structure, and the women maintain their authority because of their importance in the social economy of the tribe as planters, reapers and marketers of the crops. Thus any advance in public health must first win the approval of the women, many of whom are jealous guardians of tribal medical practices. They are largely inaccessible to teaching from medical men, especially in obstetrics, for most of them will not tolerate the presence of a man at a confinement. The one person likely to gain their ear is a fellow African woman trained as a community nurse. Dr Welch has proposed a first-year course for the student nurse in which this principle is accepted.

In her first term the student is introduced to microbiology in the manner described, to anatomy, physiology and very simple biochemistry (as a background to the understanding of nutrition), to the ways in which health can be maintained in the community and the family, to the history of medicine and nursing told like a story, and to simple nursing arts. Thus at the outset her attention is oriented not to sickness but to health and its maintenance. She is also encouraged to discuss the magical practices of her people and to see how some have aspects in common with her new knowledge, while some are dangerous, and she must be taught how to teach all this to others.

In her second term she begins the study of nutrition and of diets for infants and children, and is helped to adjust herself to the social and ethical duties of the professional nurse.

In her third term, in addition to her other studies, she learns the properties and dosage of drugs—important for a people who use active herbs in dangerous quantities in their magic—and is introduced to sick nursing and to the study of the common diseases of the country, including communicable diseases.

EX AFRICA ALIQUID NOVI

This course with its emphasis on health and prevention, on principles and practical work, might well be modified to suit English conditions and be taken by our own first-year nurses. But clearly it could never be demanded of a girl who is expected at the same time to give routine service in the hospital wards. It is a course for a student, not an apprentice. Dr Welch hopes to see African nursing freed at the outset from one of the gravest handicaps of our own system. The British student is expected to give long hours of service which prevent her from making the best use of what systematic instruction she receives; lectures attended after a day in the ward must be outstanding if they are to excite more than languid attention. The defect could be largely overcome if the nursing school existed purely to train and turn out the best possible nurses, and if it was financially independent of the hospital, which would have to be run by its own fully qualified staff. This has been tried successfully in America and Canada, and in various European hospitals established by the Rockefeller Foundation after the last war. In such a hospital in Warsaw an entire ward at a time is given over to the students under the charge of the staff of the school of nursing. All the nursing in the ward is carried out by the students, supervised by their teachers, and the cases allotted to them demand a gradually increasing degree of knowledge and skill. At the end of a chosen period the ward is exchanged for another one in which students can gain a different type of experience. Dr Welch commends this system and suggests that the hours spent by student nurses in the wards should be graded; thus they would begin by spending only one or two hours a day in the ward, the rest of the day being used for instruction in the other items of the course. The working week in the first year would occupy 29–38 hours, with Saturday and Sunday off in the first term, and Saturday afternoon and Sunday in the second and third terms; there would be a month's holiday in the year. This seems to us a reasonable study-week, in line with the hours worked by university students. We can see no excuse for the custom by which a student nurse is expected to work harder than any other class of student, nor is an eighteen-year-old girl physically fitted to spend long arduous hours in contact with the chances of infection which a hospital offers. A reform in our system of nursing to this or a comparable pattern would do much to make the profession attractive to our more intelligent girls.

THE KIDNEYS AND HYPERTENSION

EXPERIMENTAL PROGRESS

WE have known for several years that renal ischæmia experimentally produced causes hypertension in animals. Goldblatt summarised[1] the available experimental data in 1938, when it was already recognised that if such experimental ischæmia was severe enough to impair renal excretion arteriosclerotic lesions would begin to develop similar to those found in essential hypertension in man. It was clear, too, that the rise of tension was produced by some biochemical agent, not by a nervous mechanism. Since then we have learned a good deal more, thanks largely to independent groups of workers in the Argentine and in Indianapolis, and it is possible to set out briefly the points on which they agree. The normal kidney secretes a substance called renin, first described by Tigerstedt and Bergmann in 1893: renin is a pressor substance and was believed until recently to be a vasoconstrictor. Actually, the story is much more complicated than that: renin acts as a proteolytic enzyme on a globulin ("hypertensin precursor") present in normal serum, and converts it into a substance called hypertensin. The Argentine workers consider that renin only has a pressor action because it produces hypertensin, which they regard as the immediate cause of the rise in blood-pressure. The Indianapolis workers, however, have embroidered the theme by showing that hypertensin is not a vasoconstrictor itself but can only cause vasoconstriction when activated by another substance present in the blood. As if this did not make matters complicated enough, both groups of workers agree that the blood contains a substance which destroys or inhibits the action of hypertensin, and the Indianapolis group go further and say there is a substance which inhibits activated hypertensin as well. With all these substances being manufactured at varying rates it is easy to see that hypertension in man may have multiple causes.

The first step leading to the opinions just set out was the demonstration that venous blood flowing from an ischæmic dog kidney had a vasoconstrictor action on the Lawen-Trendelenburg toad preparation.[2] Moreover, if an ischæmic kidney from a dog was transplanted into the neck of another dog the second dog's blood-pressure rose[3] Again, if the renal vessels of a dog are clamped, the blood-pressure rises when the clamp is released Although these results had been confirmed many times, observers still doubted whether there was enough pressor substance present in the systemic blood to account for the hypertension Workers in Toronto,[4] however, showed in cross-circulation experiments that if blood from hypertensive dogs was transfused into nephrectomised dogs there was a transient rise of blood-pressure in the recipients They thought that other workers had failed to get this pressor effect either because too little blood had been transfused or because the receiving animals had intact kidneys (there is plenty of evidence that normal kidney tissue will inactivate the pressor substance formed in the ischæmic kidney) In their own experiments they used a special pump which ensured that the same quantity of blood passed in each direction, and transferred about 3 litres per hour Thus the substance or substances produced by the ischæmic kidney were present in the blood in sufficient quantity to cause a rise in blood-pressure The next step was to investigate these substances The Indianapolis workers showed that renin in Ringer's solution did not constrict the blood-vessels in an isolated dog's tail[5], when blood was added to the solution, however, vasoconstriction occurred Thus it was clear that renin alone had no pressor effect it acted on some constituent of the blood to produce a vasoconstrictor substance This is the substance which the Argentine workers had called hypertensin, the Indianapolis workers unfortunately named it angiotonin,[6] thus adding verbal confusion to a subject already reasonably tricky From accounts of the properties of the two substances there is little doubt that they are identical, and the earlier term "hypertensin" will be used here Both groups of workers demonstrated[6,7] that renin acted on a globulin—found in the blood but not in other tissues—to produce hypertensin, and that hypertensin had a smaller molecule than its precursor They also showed that the concentration of hypertensin produced depended on the amount of the globulin present and was largely independent of the amount of renin, and this, together with the facts that renin is heat labile and acts best at a given pH, suggested that it was a proteolytic enzyme Some of the Indianapolis workers isolated a crystalline picrate and oxalate of hypertensin, but give no melting points or elementary compositions in their paper The Argentine workers[8] find that hypertensin is inactivated by pepsin, and regard it as polypeptide, though it is reported from Indianapolis to give a negative biuret reaction The Argentine workers find that when renin is incubated with blood the hypertensin content first increases rapidly, then diminishes and finally disappears, this is held to be due to the action of an inhibiting substance called hypertensinase Since hypertensinase is also heat labile and has an optimal pH for its action, it too may be regarded as an enzyme Other observations are that hypertensin-precursor is diminished by injection of renin and increased by nephrectomy, and that nephrectomy also decreases the hypertensinase present in the blood These observations explain why nephrectomised animals are more sensitive than intact ones to both renin and hypertensin, and also why animals soon develop a tolerance (tachyphylaxis) to repeated renin injections but not to repeated injections of hypertensin These findings agree in general with those of the Indianapolis group, who have further shown[9] that hypertensin in Ringer's solution produced vasoconstriction in the isolated rabbit ear only on the first trial or two, after these trials, the vasoconstrictor action was lost, and was only recovered when fresh blood was added to the perfusing fluid Hence arose the conception of a hypertensin-activator If blood from nephrectomised dogs is used in such perfusion experiments, the vasoconstrictor activity of the hypertensin is greater than it is with normal blood, yet the effect with normal blood is maximal in the sense that no increase in vasoconstriction can be produced by increasing the amount of blood used in the experiment Thus it can be supposed that there is an inhibitor substance present in normal blood which is diminished by nephrectomy There is evidence that this substance is not hypertensinase

Hypertension, then, may be produced by increased production of renin, hypertensin-precursor or hypertensin-activator, or by decreased production of hypertensinase or hypertensin inhibitor, or by combinations of any of these factors The existence of hypertensinase and hypertensin-inhibitor offers a hope of a method of treating human hypertension, and already at least three reports have appeared recording lowering of blood-pressure in animals and in patients with hypertension The extracts of kidney used have been essentially similar and the amounts high The extract from 100–150 g of pig kidney has been given daily by Jensen and his colleagues[10] to lower the blood-pressure in rats with experimental hypertension, this figure is slightly lower than that given by Page and his collaborators,[11] who show that the extract from 1000 g of fresh kidney may have to be injected daily for some weeks to improve patients with malignant hypertension The claim of Grollman and others[12] that oral administration is effective in rats has not been confirmed by other workers The rat does however provide a convenient animal for experimental assay so that chemical advances may be speeded, and it is on these advances that clinical application must at present wait

Infectious Disease in England and Wales

WEEK ENDED OCT 25

Notifications —The following cases of infectious disease were notified during the week smallpox 0, scarlet fever 1224, whooping-cough, 1985, diphtheria, 1017, paratyphoid, 53, typhoid, 23, measles (excluding rubella), 745, pneumonia (primary or influenzal), 631, puerperal pyrexia, 143, cerebrospinal fever, 88, poliomyelitis, 50, polio-encephalitis, 4, encephalitis lethargica, 2, dysentery, 139, ophthalmia neonatorum, 77 No case of cholera, plague or typhus fever was notified during the week

The number of civilian and service sick in the Infectious Hospitals of the London County Council on Oct 22 was 1287, including scarlet fever, 167 diphtheria, 280, measles, 20, whooping cough, 511, enteritis 22, chicken pox, 23, erysipelas, 28, mumps, 3, poliomyelitis, 6, dysentery, 18, cerebrospinal fever, 16, puerperal sepsis, 12, enteric fevers, 42, other diseases (non infectious) 47, not yet diagnosed, 92

Deaths —In 126 great towns there were no deaths from measles or enteric fevers (1 from enteric in Greater London), 2 (0) from scarlet fever, 16 (2) from whooping cough, 31 (3) from diphtheria, 56 (3) from diarrhœa and enteritis under 2 years, and 15 (0) from influenza The figures in parentheses are those for London itself

Fatal cases of diphtheria were scattered over 19 great towns Liverpool reporting 4 There were 8 deaths from diarrhœa in Manchester and 7 in Birmingham

The number of stillbirths notified during the week was 176 (corresponding to a rate of 32 per thousand total births), including 20 in London

---

NUTRITION IN IRELAND —The *Irish Press* of Oct 17 announces that a dietetic council has been set up "to experiment on ways and means of aiding the people's nutrition under war time conditions, paying special attention to children's diet" The following have been appointed Dr P T O'Farrell (chairman), Prof W J E Jessop (secretary), Prof W R Fearon, Dr Catherine O'Brien, Dr John Mowbray and Dr Oliver FitzGerald

Public Health

Future of the School Medical Service

Dr E H Wilkins[1] has lately suggested some reforms to improve the school medical service and make it coherent with any general plan for a complete medical service for the nation He divides the existing defects of the school service into those remediable by changes within the sphere of the service itself or of public hygiene, and those which are bound up with the progress of general social welfare The school medical officer, unlike his colleagues in other branches of the profession with the exception of the obstetricians, deals mainly with people who are, or are presumed to be, healthy, so most of his work is more closely allied to social amenities than to the treatment of the sick Yet he came into existence with the object of doing work which is strictly medical—to detect and obtain treatment for children who were unhealthy and who, in the state of medical practice as it was 35 years ago, missed the attention of the family doctor which they should have received He has always been difficult to place in the medical hierarchy and in consequence occupies a somewhat low position though in fact his work is now the highest objective of the medical profession Wilkins takes the view most generally held that the school service should be incorporated with the other health services, the medical officer of health being the chief school medical officer and the assistant school medical officer also assistant medical officer of health The advantages of this system are fairly obvious, but it has several drawbacks James Kerr pleaded consistently for the separation of school medicine from general public health, though his immediate successors who were independent of the public-health office were in general not in favour of the separation The objection to the fusion is that school medicine has become highly specialised, to be successful the practitioner must give his life to it, and it is not in the interest of the work or of those who undertake it that school medicine should be a side issue and a stepping-stone to general public health The advantages of liaison of school work with other public-health functions, especially with infant welfare, outweigh *all* possible disadvantages so far as the service is concerned, but the subsidiary position of those who do the school work is against its development A matter which gave rise to much contention in the past is the relationship of school medical officers with general practitioners School medicine was one of the first and certainly the greatest of the encroachments of public medicine on private practice This controversy has died down for a time, but it will come up again should the planning of the future of medicine develop on the lines of national health insurance Specific medical treatment is *no real* part of school medicine, but supervision and management of children certainly is, and there is no fixed division between what is treatment and what is management

The reforms needed in the technical part of school medicine must be left to the school medical officers themselves to settle The discussion over the value of periodic medical inspections, in which Wilkins is emphatically in favour of their retention with several modifications, can be understood only by those who are familiar with the work and with its aims, but the pursuit of its aims calls for great reforms in the social welfare of the people, for poverty in all its aspects and implications is the great stumbling block to the maintenance and development of health Most of the work of school medical officers is among normals, by which is meant average samples, and its failure has come from confusing normality with full health, a mistake made constantly in all medicine, for we have so little experience of full health that we can hardly be said to know what it is like We see this mistake outstandingly in the assessment of nutrition, about which Wilkins has much to say However we may define nutrition, it is certain that the vast majority of children are round about the normal, but it is equally certain that few if any of the normals are in the state of maximum nutrition which alone is the state of health The achievement of this maximum does not lie within the province of medical attention, but in obtaining the best environmental conditions, especially during the period of development Wilkins says truly "The implication that the classifying of 90% of children in the first two of the Board's categories ("excellent" and "normal") indicates that these children are well fed is sheer nonsense, conflicting as it does with a mass of evidence based on ascertained fact" The object of school medicine is to raise the standard of normality in all particulars so that it approaches nearer to full health This of course calls for some treatment which the medical profession can furnish, but far more for social treatment to raise the level of general environment

From the Annual Reports

CHELSEA

From Dr Leslie McCarthy's brief report for Chelsea we learn why the population shrank from the 1939 figure and the death-rate rose "Other violence," mainly war casualties, caused some of the total of 851 deaths Of the other deaths, 204 were due to heart disease, 106 to cancer and 68 to vascular lesions This suggests that the population of Chelsea which stayed was elderly As Chelsea was an evacuation area throughout the year the average population will have been less than the mid-year population, so the true death-rate, whether crude or corrected, will be higher than the 22 recorded What was the standardised rate, which alone reflects the health of the population, will never be known

EASTBOURNE

This county borough was a reception area in the first half of the year and an evacuation area after the fall of France since when it has been a restricted area In contrast to Ramsgate it suffered little from air-raids, and because it has always been more of a residential town for retired people than a holiday resort it has suffered less from the loss of its visiting population than other coastal towns Dr J Fenton's report for 1940, though typewritten and curtailed, does not therefore differ greatly from peace-time reports, and from it one could not tell that there had been any serious disturbance in the town's history except for a decline in the population The increases in the infectious diseases noticed at the end of 1939 did not continue, with the exception of scabies Whooping-cough gave 159 notifications, 126 of which occurred in the first quarter, and none in the last four months of the year, and measles 105 notifications, 57 of which occurred in June–August These seasonal incidences were unusual, for in the country as a whole whooping-cough increased and measles diminished as the year progressed There was no death from either disease

RAMSGATE

Dr J V Walker's report is of exceptional interest for in the latter half of 1940 Ramsgate was in a state of siege and subject to repeated air attacks on a heavy scale In peace-time its population was made up of an unusual proportion of elderly people, and in view of the danger of invasion an evacuation scheme for them was instituted It was expected that this would be made compulsory, but it was not, so the process of getting the old away to safe areas was both lengthy and incompletely successful Evacuation of mothers and children offered no special problems, but as the risk of invasion came suddenly it had to be hurried The normal population of Ramsgate is 34,000, but the statistics are of course based on the estimated population in the middle of 1940 The growth of a troglodyte population in the famous tunnel shelters might have been expected to influence the town's health, but it is doubtless thanks to them that the casualty lists were so small Of the 490 deaths registered in the town in 1940 the heading "other violence" includes civilian deaths from enemy action Elsewhere shelters were used as dormitories but at Ramsgate a small proportion of the population shifted their homes underground and seldom came out of the tunnels at all There was little excuse for this since owing to the evacuation there was ample accommodation In view of all this we should expect a very unfavourable health record for the town, but excluding the casualties there is no evidence that the town's health has suffered Indeed, the year's record is that of a healthy year with low prevalence of communicable diseases There were no deaths from the typhoid or dysentery groups of diseases and only one death from diarrhœa in an infant of six months The respiratory deaths numbered 65, but 49 of these were ascribed to bronchitis, suggesting that the comparatively high rate arose from the age of the population and not a high prevalence of respiratory infections

In England Now

A Running Commentary by Peripatetic Correspondents

I OFTEN try to read a newspaper and listen to the wireless at the same time and generally end up by missing the point of both Of course there are fellows who can play a dozen games of chess at once and could probably read and listen to a story or two as well, but I'm not one of them I can't listen to even two tales at once The other evening I went in to have my pint in the bar parlour of the Locums' Arms This is where the locums rest between engagements, and there were several there, grousing and drinking On my right an old locum was holding forth to a friend and over in the corner was a young locum doing the same thing "Some people," said the Old Locum, "take to war-time rationing con amore" He wiped the froth meditatively off his walrus moustache "Yes, for other people My last engagement was a seaside job of three weeks The man had gone away for a holiday, but his wife who was a part-time invalid stayed to look after me, leastways that's how they put it Well for the first breakfast I had a sardine on toast, one Same thing the next day and the next I fed alone, but used to see savoury trays—eggs and bacon from the smell—being hurried furtively upstairs The lady didn't come down till midday 'Oslo breakfast,' she said one day, 'so healthy!' 'How I wish I were up to them!' said I 'I had no idea they were having quite such a terrible time in Oslo Do you mean to tell me they have only one ?'" Then I heard the Young Locum's voice away in the corner "It was only a week's locum, the whole family were going away for a holiday Before he went the doctor said to me, 'We're having the house done up a bit, hope you won't be disturbed' Next morning the cook asked if I would mind having lunch in the drawing-room as the whitewashers were in the dining-room, and sleeping in another bedroom Next day it was would I mind having meals in the study and sleeping in the nursery On the fourth day I was having meals in the surgery and sleeping in a dressing-room, but next morning they were both seized by a whole army of painters, paper-hangers, carpenters and whatnot, in fact they had the whole house now except at the very top where there were two rooms, the cook's and another Of course I had to sleep in the other and heard her snoring Well, I thought they were going to leave the top storey alone, but I had scarcely finished dressing when the vanguard of this renovating army " "It wasn't as though there was any shortage of food in the house"—it was the O L that I was listening-in to now—"the cupboards in my bedroom were simply crammed with tinned meats, jams, pickles, masses of it Well, it must have been about the sixteenth day and I was getting well into the third row of that tin of sardines " "Apparently" (Y L speaking) "they weren't going to touch the cook's room, so I was wondering " "My stomach was definitely in revolt, that damned fish repeats itself like a parrot, so that morning on my rounds I stopped at a shop and bought a tin-opener " "Well, the cook came along as usual and said would I mind " "By Jove, that night I fairly let myself go" Who said that? I'm not sure It may have been both together "Time, genelmen, please"

* * *

We have noticed four classes of faint among our donors Those who throw the first or fourth class should never have been enrolled because they are temperamentally unsuitable the second variety (a "forme fruste" of the first) is preventable with careful handling, while the third must be attributed to mismanagement of the donor after the withdrawal of the blood

The first class is seen in the extremely apprehensive donor who may have volunteered from self-disciplinary or purely altruistic reasons, or may have been pressed into service in the presence of his colleagues or f Such a person may faint in the waiting-room or on couch while his arm is being cleaned up At one f some youths flopped down like ninepins while their turn to be grouped The sight of bottles of drawn blood or blood-stained gowns, too much thea ritual or the smell of ether (acetone is not associated by the patient to the same extent with hospitals) may preci-tate the faint This type of person should never hav volunteered and if he is recognised at the time of enrol-ment he should be rejected

The second class turns up in the person who does no mind the beginning (indeed he may be quite interested and will try and sit up and have a peep at the blood running out) but after a few minutes a feeling of nervousness comes over him, an occasional sigh, a rapid turn away of the head, and a nervous cough are the first sign He begins to think "will they be able to stop it?" If the doctor leaves the needle in situ and goes away to prepare the next patient, the feeling of insecurity will continue to thrive During a brief period of hyperacusi he will hear his blood trickling into the diluent in the bottle and he may hear the nurse say "Its running ever so fast I wish they all bled as quickly as this" The actual faint will follow rapidly and the flow of blood will diminish reflexly This type of donor has probably fought a strong inclination not to show up for his appointment and he sometimes tries to pass off his nervousness with forced merriment and interest, hence his desire to "have a look" and the occasional pleasantry whereby the shed blood is compared to a favourite brand of stout With care, this type of donor, who can often be recognised when he comes in by his jocularity and the excessive pulsation of the great vessels of his neck, can be successfully bled, for he will readily take the initiative in conversation which interests him The doctor should not leave him unattended and mentally unoccupied, while assistants should be discouraged from making comments and quips on the rate of flow A word of encouragement will help him through his ordeal, and the doctor will be rewarded by "Is that all it is?" and a pressing and genuinely meant request to call him again

The third kind of faint is a vasomotor attack probably beyond the control of the donor It is as a rule due to sitting up suddenly and too soon to drink coffee presented by an overzealous helper This type of faint will also occur, without the donor sitting up, if the blood is withdrawn too quickly Fasting will also tend to induce it likewise if the donor is overtired, or has hurried to be in time, or if the atmosphere of the room is oppressive Some people seem to take longer than the average to adjust their circulations and we have seen this tendency in a mother and daughter who were each unaware of the reaction of the other

The last class is troublesome, it is the hysterical faint induced whenever an impressive audience is available The subject is almost invariably a young girl and she should be allowed to faint into the arms of a member of her own sex A favourite place is in the street outside the bleeding post and unless the offender is skilfully and promptly handled the post and the team may be held in considerable disfavour and distrust by the cross section of the public who congregate so rapidly for this windfall entertainment We have seen a husband and wife (only the wife had volunteered) go from one "fit" into another, falling into any kindly arms willing to receive them and causing confusion and consternation among the volunteers in the waiting-room By the way, it does not seem to be generally known that faints, if complete, may take on an epileptiform character They can, however, readily be differentiated from hysterical attacks The act of fainting is commonly followed by a feeling of tiredness and this may be attributed by the donor—and what is more important, by his friends—to the loss of blood A donor who has fainted should always be warned against this feeling of tiredness, and for the same reason it is unwise to continue withdrawing blood after a faint has begun Donors should be warned of the possibility of bruising, and of bleeding starting again, and should be told how to deal with bleeding by pressure They should be warned not to touch the dressing unless the wound is painful and then to show it to a nurse or a doctor Over the tea-table, when the donor has returned home, she will probably be invited to relate her experiences and the kid brother and his friend will certainly want to have a peep at " the hole in the arm ' This understandable curiosity is probably the comonest cause of local sepsis

* * *

It has taken a second world war to convince me that pectoralis major is intimately concerned in the act of defæcation But I must begin at the beginning My gardener was called up last year and I was obliged to tackle a third of an acre singlehanded. I mow the lawns every three weeks This represents the optimum interval on a time-growth curve which I have worked out for this part of the country the fourteen-inch mowing machine of the 1920 age-group has been carefully integrated to other variables About a fortnight ago I was rushing downhill behind the machine my eyes fixed on a luxuriant tuft of grass which I intended to cut as clean as a whistle I allowed the blades to engage when I was about two yards from my objective and with savage determination threw myself into the attack on the waving green spikes A sudden crack, and I found myself staggering across the lawn gasping painfully for breath and rubbing my chest in the region of the second left costal cartilage where I had collided with one handle of the mower I had forgotten that behind that innocent tuft of grass there lay hidden a small grid covering a drain ventilator "Pooh!" I exclaimed but the explosive was cut short by a stab of pain which made me hold my breath I sat down gingerly on the lawn lowering myself on extended arms, but the manœuvre ended in a groan I would have sat longer but there were unmistakable sensations indicating that the grass was not as dry as I had imagined To immobilise the injured muscle I decided to raise myself using only my right arm But seemingly the pectoral girdle never does things by halves and I was conscious that it had gone into action even while I was at the stage of visualising the extent of the wet patch on the seat of my trousers The next day was full of discoveries, including the one mentioned in my opening sentence Fortunately there was little cause for the turbulent movements of the thoracic cage which are associated with laughter, and a suppressed cough was usually achieved by fixing the left side of the chest against the edge of a door The sigh over the blackout was stillborn and the bedtime yawn hovered in midair. As for the night, it was made hideous with moans which synchronised with attempts to change my position in bed Great though my discomfort was, I little realised that worse was in store I was in the bus on my way to hospital Suddenly I was aware that the awful thing was about to happen It was too late to avert the impending catastrophe I whipped out my handkerchief, being a faithful disciple of Bourdillon, and there followed a gigantic sneeze The pains of hell got hold upon me and the explosion merged into an involuntary roar of anguish The bus stopped The driver s terrified face appeared at the hatch anxiously seeking an explanation from the conductor I have since thought that he must have been driving in a dream state and on hearing the cry had leapt to the conclusion that he had run over a pedestrian He was reassured by the young woman who was our conductor. amid a muttered chorus of disapproval from my startled fellow passengers she erked her thumb in my direction " It s 'im " she said imply On arrival at the hospital my first call was at he radiological department Sister, full of sympathy offered to send the report to my ward as soon as the adiologist had reported on the film An hour later it was handed to me in a sealed envelope I opened it agerly, impatient to learn how many ribs had been broken My colleague had confined himself to a single word NIL "Pshaw!" I exclaimed wincing with pain

* * *

I was a very puzzling case On Sunday I lost my ppetite and felt off colour Next afternoon I had a dull headache behind the eyes which slowly got worse On Tuesday evening I felt shivery and had a tempera-ure of 100° F Taking a couple of Veganin tablets nd a stiff hot whisky I went to bed early only to be wakened at 4 A.M. by persistent shivering in spite of piling all the garments I could find on my bed, and by A M I felt so ill I decided to stay in bed That evening felt colder than ever in spite of numerous hot-water bottles and had an awful headache My temperature had risen to 103°. my pulse to 130 and I had developed a sighing type of respiration at 36 a minute I felt increasingly sick and was the vomitus being dark brown and dirty and very acid to the mouth I thought I was in for a bout of pneumonia and so did my physician for he examined my chest five times Even morphia that night failed to ease the intense headache and I barely slept at all, perspiring periodically Thursday was even worse, although the headache was easier all morning I was sick several times and kept up an irregular fever I was now convinced that I had meningitis, but on pointing out to the physician that my eyes were tender if touched he rushed off to get his ophthalmoscope when being a mere surgeon I now thought I had a retrobulbar neuritis That night was just as bad By Friday morning I was past caring My mouth was thick and dry and my lips were coated with sticky mucus Having no neck rigidity I now diagnosed myself as influenza with encephalitis My physician was still in the dark, but he arrived with great glee to say that a blood-count showed a leucopenia , therefore I must have influenza, unless of course it was typhoid or one of that lot He re-examined me and with a shout of triumph announced I had " rose spots " but still had no palpable spleen Not having had my bowels opened throughout he ordered me an enema I strained all day and by the evening felt a little better if somewhat exhausted My headache was easier but my rash which did not itch at all, had become diffuse all over my trunk and looked like scarlet fever I had a very white tongue but no sore throat and the rash did not involve my head and neck or limbs A blood-culture was taken that afternoon On Saturday morning I felt better still and only had a temperature of 99°, though the rash and headache persisted The pathologist announced he had grown a gram-negative bacillus, which was supposed to clinch the diagnosis of a septicæmia of the coli-typhoid group—but it struck me that a mere 14 hours' incubation in ox-bile medium with blood that had been immunised months previously with TABT made it sound unlikely Otherwise I must have a considerable infection or ,very potent bacilli My father also a doctor was certain I was a typical atypical (he is Irish) case of scarlet fever By Saturday evening I had a dusky irregular macular rash on all my limbs—not at all like " rose spots " but rather like measles However tired I was in the evening I became peculiarly alert by night and found it almost impossible to sleep Saturday night was no exception and I did not sleep at all though I managed about 1½ hours after breakfast on Sunday morning During that day my headache left me entirely as did the rash on my trunk, though on my limbs it remained until nightfall and itched The margins of my eyelids felt sore and I felt a strange kind of stiffness almost a cramp, in my calves and thighs if I moved my legs at all That night, helped by 10 grains of Medinal and an extremely comfortable Sorbo mattress supplied by the American Red Cross I had a full night s sleep for the first time On the Monday I awoke refreshed and enjoyed the pathologist's report that all subcultures had died out The final proof had failed Some " friends " suggested it must be *Bact suipestifer* or swine fever! Next day I was normal in every way and felt darned peckish, so that on the Wednesday I was allowed up for an hour On the Thursday Friday and following Monday the pathologist cultured my stools and urine and found no pathogenic organisms I was discharged on the 13th day after taking to my bed and on the 15th day from my first symptom Later my Widal reaction taken on the 22nd day from my first symptom gave a weak double positive result:

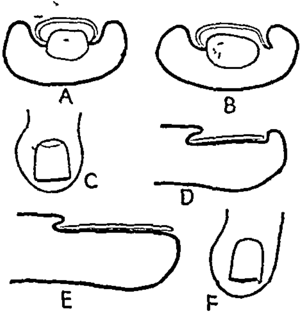
MISS T MONTAGNON who died on Oct 27 at the Westminster Hospital, had been an inspector for the Ministry of Health since 1920 She was one of the first trained nurses to be appointed to the staff of the ministry and had done much to help public assistance authorities to maintain a high standard of care for the old people and children in their institutions

Letters to the Editor

INGROWING TOENAIL

SIR,—Before any further suggestions are made as to the cause of ingrowing toenail it might be well to ascertain the true shape of the big toenail It is a laborious job to collect facts of such apparently trivial importance, but anyone who cares to investigate will discover that in some cases—I have no idea whether the proportion is small or great—the normal shape of the nail is as in (*a*), while the ingrowing nail is really a nail which grows *out into* the nail wall (*b*) Apart from any question of abnormality of the nail shape we have to remember that many people habitually cut the nail too short (*c*), so that the soft tissues grow to a higher level than the free edge of the nail and form a distal pseudo-wall (*d*) A well-cut nail extends to the end of the toe (*e*) and prevents the formation of this pseudo-wall Finally, mistakes are often made in the cutting of the nail The correct shape is a straight line and not curved as in the case of the fingers When a toenail is cut with a curve it is easy to miss the corner—probably owing to the lateral curvature This results in a spike (*f*) which, as the nail continues to grow, perforates the distal pseudo-wall The sequence—wound, infection, inflammation, septic ingrowing toenail —is obvious.



Manchester W SAYLE CREER

LIGATION OF THE PATENT DUCTUS ARTERIOSUS

SIR,—In their paper of Oct 18 Dr Bourne and his colleagues mention that two dangers of a patent ductus arteriosus lie in the mechanical effect on the circulation and the local supervention of infection, and they consider that ligation of the duct should be adopted as a therapeutic measure for the latter complication There seem to be grounds for doubting the importance of these asseverations Persistence of the ductus arteriosus may exist as the sole abnormality in about a quarter of the cases, and it may then cause no inconvenience, for the right ventricle merely hypertrophies in order to deal with the increased volume inflowing through the patent channel as a result of the higher aortic pressure The sum total of change therefore in this type of case is that right ventricular development equals or exceeds that of the left and may be accounted as a physiological response to increased work and unlikely to give rise to mechanical strain on the circulation In the majority of cases however the condition is associated with other congenital abnormalities, usually of an obstructive type, in the pulmonary or aortic circuits, and its presence is then of the utmost importance in permitting the establishment of a functional readjustment of the abnormal blood-flow In such instances it is obvious that ligation of the ductus arteriosus would constitute a grave threat to the compensatory collateral circulation, a danger which is not lessened by the fact that the detection of additional congenital abnormalities may be very difficult Thus it may be seen, in connexion with the first case, that the continuous murmur of ductal origin was replaced later by a rough systolic one in the pulmonary area, thereby indicating the unsuspected co-existence of a stenotic lesion No doubt the lesion was of a minor character, yet the operation was followed by a severe though fortunately temporary uræmia and the incident serves well enough to illustrate what may happen in a more complicated type of case

The connexion between endocarditis and patent ductus arteriosus is undoubted Nevertheless, it may be questioned whether ligation can have any good effect either preventively or curatively, as the underlying predisposition to infection must be based on the anomaly of anatomical structure rather than irregular circulatory flow and the operation will not alter that factor As a curative measure the value of the operation is still problematical, since the vegetations in general are limited to the ductus and the underlying structural defect in the wall of the pulmonary artery is not remedied Indeed, the only practical accomplishment achieved would be a reduction in the number of systemic emboli, if these were present, to the ill vantage of the pulmonary circuit which would thereby receive the full complement Recovery from infective endocarditis is not unknown even before the days of sulphonamide treatment, and there is no means of ascertaining in the two cases described whether the operation in any way influenced the course of the disease as both patients were afebrile and on the road to recovery before it was carried out It may be that there is a case for ligation of the patent ductus arteriosus, if there is, it would not appear to lie in that class of patients, comprising the majority, associated with other congenital cardiac defects or in any after the onset of infection In the remainder, a logical indication for ligation might be as a prophylactic measure, but, in view of the natural repugnance of the healthy person to undergo "ideal" operations, particularly major ones, it is possible that opportunities to assess its real value will be few

London, S W 3 J H MULVANY

CALCIUM STUDIES IN NORMAL PEOPLE

SIR,—I have been reading Dr Robertson's articles with great interest He quotes figures from balance experiments conducted on normal subjects which showed that below a certain level of Ca intake the Ca output was restricted—i e, the Ca was used more economically In the cases he quotes, the subjects had been on the low Ca intake for only short periods We found the same in indigent subjects who had been on a low Ca intake for long periods (Owen, E C, Irving, J D and Lyall, A *Acta med scand* 1940, **103**, 235) So efficient had the utilisation of Ca by these subjects become, that some of them were in equilibrium on intakes as low as 0 25 g Ca per day It would appear from this and other work (i e, Rottensten, K. V *Biochem J* 1938, **32**, 1285) that one cannot define a *normal level of Ca intake* in this way since the requirements for equilibrium will depend solely on the Ca reserves of the individual under test, and these in their turn depend on *the previous* dietary Ca history This has recently been stressed by Steggerda and Mitchell (*J Nutrit* 1941, **21**, 577) Thus it has been found that Chinese (Kung, L C and Yeh, H L *Chin J Physiol* 1937, **12**, 139) and negroes (Kelly, F C and Henderson, J M *J Hyg Camb* 1930, **29**, 418) appear to have a lower requirement for Ca than do white people This lower requirement is certainly not racial in origin but is due to the fact that these peoples habitually subsist at lower levels of Ca intake (Kung and Yeh) It therefore seems to me that one cannot quote figures for normal Ca requirements on the basis of balance experiments since the requirement for *equilibrium depends entirely on the previous dietary history of the individual* The only assessment of adequate Ca intake must be an empirical one—one which keeps the individual in optimal health

J T IRVING

Department of Physiology, University of Cape Town

"WAR-TIME HEALTH AND DEMOCRACY"

SIR,—May I take up two points in your generous review of my small book in THE LANCET of Nov 1? Lord Hewart's definition of democracy is "a system of government based on the Rule of Law and the Sovereignty of Parliament" your reviewer has telescoped the sentence in my book which gave this definition, and the result is hardly fair to the distinguished author of "The New Despotism" Your reviewer gives one or two selected quotations to support his argument that I have "a somewhat introverted view of the doctor as a democrat" Two more quotations, if you will allow me to give them, cast doubt on your reviewer's interpretation "My own opinion is that the doctor, *in relation to his professional work*, should steer clear of politics" (Italics mine) "And the individual doctor can always express his political views as a *private citizen* with the right to vote for his man in a free country" (Italics mine again)

London, W C 1 HUGH CLEGG

PLUMP TYPE OF GRAVES'S DISEASE

SIR—In commenting on our paper of Sept 20 Mr Keynes makes the rather surprising statement that "it is dangerous to make any attempt to separate off any particular category [of Graves's disease] as being fundamentally different from the rest" Mr Rundle in your issue of Oct 25 appears to support this view The cases we described had one distinctive character uncommon in Graves's disease—a tendency to increase in weight while still untreated and actively thyrotoxic In addition they were all young women of about the same age with an unusual degree of lymphatic hypertrophy even for Graves's disease, and five out of eight had amenorrhœa It seemed to us that these cases formed a distinctive group though we admitted the existence of transitional types, and we suggested that they were displaying an unusual resistance to the thyrotoxic process Since the results of thyroidectomy had not been so satisfactory as we had come to expect in the usual type of Graves's disease, we ventured to suggest that in such cases conservative treatment might be given a trial We presume that it is this mild suggestion which has so alarmed Mr Keynes

Mr Keynes has also made much of the two deaths in this group We did not of course draw any far-reaching conclusions from these deaths, they were never a major point in our discussion on this group and it will not surprise us if further experience shows the mortality to be not unduly high None of the surviving cases, however could be classed as good results, and three of them were early recurrences

Later Mr Keynes himself braves the dangers of subdivision sufficiently to admit the existence of "atypical" categories of Graves's disease among which he classes the plump type This surely is an odd method of classification, for he presumably groups together all cases which happen to lack one or more of the chief characters of the disease We can see little in common, for instance, between the plump type (which are severe and outspoken examples of Graves's disease in young women) and the type common in the elderly in which auricular fibrillation is the only prominent feature of the disease Yet Mr Keynes would apparently class these groups together as "atypical" categories Of this oddly assorted group, Mr Keynes says that "there is room for judgment in forming an opinion for or against operation" because the results of thyroidectomy are less dramatic than in the classical type Whether this is a correct statement of the prognosis of this remarkable hotch-potch it is impossible to say, but the statement is interesting as revealing that even Mr Keynes considers the results of thyroidectomy to be not always exactly predictable If this is so, is it so very dangerous to inquire whether there are not in fact different types of the disease, which may respond characteristically to treatment?

To avoid further confusion, the conclusions arrived at in our paper were the result of careful observation over a number of years of a series of cases of Graves's disease, operated on by the senior surgical staff at a general hospital Mr Rundle's reference to "a surgeon's early efforts at thyroidectomy" is therefore irrelevant

GRADUATION AT AN EARLIER AGE

SIR,—Many will agree with Dr Spencer Paterson, who pleads for graduation at an earlier age in your issue of Oct 25, when he states that the years from sixteen to eighteen are not very usefully employed But surely the chief reasons are not, as he suggests, that students are either learning subjects which they must later re-learn at the university, or are learning classics because, at the age of seventeen, the great majority are already working for their first M B Rather these years are not usefully employed because the work must conform strictly to a university syllabus which demands an unnecessary amount of detail, and does nothing to encourage a general or scientific background Added to this, in many cases, are the unnatural restrictions to freedom and independence imposed at this stage by the public-school system

To justify his plea Dr Paterson also referred to the undesirability of late marriages and small families among the medical profession This is found in the professional classes as a whole and the reasons are largely economic For this the state is responsible and the state must find the cure, not the university or the medical authorities to whom the plea was directed And let us note that the one state that has tackled this problem provides medical men even in their student days, with an adequate salary. I cannot help feeling that the moral breakdowns in medical students which Dr Paterson is apparently called on to treat may be due not so much to frustration with the medical curriculum as to the realisation that at the age of twenty-one they are still and for the next few years will remain just as dependent on their parents for their every need as they always have been

I submit Sir, that our efforts would be better directed towards changes in the medical curriculum and in the status of the young doctor, than towards graduation at an earlier age Superficially this suggestion may appear as a panacea for the ills to which Dr Paterson so rightly pointed But perusal of your number (Aug 30) devoted to medical education will show that in this country graduation probably takes place already at an earlier age than in any country in the world with the exception of Nazi Germany

THE HEN AS MIDDLEMAN

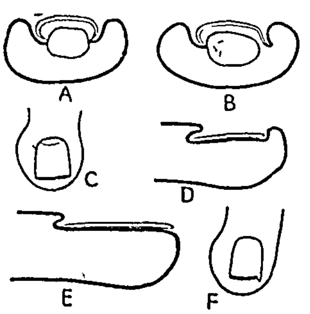
SIR—I welcome the criticism that appeared in your issue of Oct 25 (p 487) on my article in *Nature*, although the suggestion that, being an authority on poultry, I naturally defended the animal of my choice from the obloquy cast on it by agriculturists and dietitians is not too happily phrased since the casual reader may assume that I wrote the article from reasons of self-interest rather than from the point of view of the welfare of the nation In my article I contended that, on dietetic grounds the egg is just as essential an article of diet as milk and that, from the point of view of economy of conversion of feeding-stuff protein to human food protein, the hen has a claim to priority second only to the dairy cow I assume that this dietetic part of my contention is accepted But you attempt to destroy my case for the hen on economic grounds Not being an economist I am at a disadvantage, but even to my amateur mind the arguments adduced appear a little unsound To base an argument on the relative price the Government is prepared to pay for the protein in eggs and milk in these days of price regulation, and to argue that such prices reflect the relative efficiencies of the dairy cow and the hen to produce such protein is surely illogical, apart from the fact that I have never suggested that egg production should be encouraged at the expense of milk production The present prices paid to the producer by the Government are admittedly fixed in relation to cost of production, but such costs cover many other factors than that of relative efficiency of food conversion The relatively high prices paid for eggs are essentially due to the fact that Government action has resulted in poultry producers having to cut their flocks below the normal economic level whereas no such action has been enforced in the case of the dairy farmer The price argument works both ways Following the same line of argument I could with equal justice maintain that the Government by asking the consumer to pay 2½d for an egg containing 6–7 g of first-class protein, as compared with a pint of milk at 4½d containing 18 g, is of the opinion that egg protein is much more valuable to the consumer, weight for weight than milk protein

The contention that the hen being a much smaller animal than the dairy cow, requires much more energy for maintenance than the dairy cow weight for weight, is an accepted fact, but even here there is a possible fallacy in the argument, since the relative cost of maintenance when charged against the finished product, will vary according to the relative amounts of the finished product produced It is of interest to note that a 5 lb hen laying 140 eggs a year produces 78% of her body-weight in the form of dry human food (not counting shell) whereas the 1250 lb cow giving 600 gallons of milk produces only 59% of her body-weight in the form of dry human food Finally, although the energy requirement for maintenance is correlated with body surface rather

Letters to the Editor

INGROWING TOENAIL

SIR,—Before any further suggestions are made as to the cause of ingrowing toenail it might be well to ascertain the true shape of the big toenail It is a laborious job to collect facts of such apparently trivial importance, but anyone who cares to investigate will discover that in some cases—I have no idea whether the proportion is small or great—the normal shape of the nail is as in (*a*), while the ingrowing nail is really a nail which grows *out into* the nail wall (*b*) Apart from any question of abnormality of the nail shape we have to remember that many people habitually cut the nail too short (*c*), so that the soft tissues grow to a higher level than the free edge of the nail and form a distal pseudo-wall (*d*) A well-cut nail extends to the end of the toe (c) and prevents the formation of this pseudo-wall Finally, mistakes are often made in the cutting of the nail The correct shape is a straight line and not curved as in the case of the fingers When a toenail is cut with a curve it is easy to miss the corner—probably owing to the lateral curvature This results in a spike (*f*) which, as the nail continues to grow, perforates the distal pseudo-wall The sequence—wound, infection inflammation, septic ingrowing toenail—is obvious.



Manchester W SAYLE CREER

LIGATION OF THE PATENT DUCTUS ARTERIOSUS

SIR,—In their paper of Oct 18 Dr Bourne and his colleagues mention that two dangers of a patent ductus arteriosus lie in the mechanical effect on the circulation and the local supervention of infection, and they consider that ligation of the duct should be adopted as a therapeutic measure for the latter complication There seem to be grounds for doubting the importance of these asseverations Persistence of the ductus arteriosus may exist as the sole abnormality in about a quarter of the cases, and it may then cause no inconvenience, for the right ventricle merely hypertrophies in order to deal with the increased volume inflowing through the patent channel as a result of the higher aortic pressure The sum total of change therefore in this type of case is that right ventricular development equals or exceeds that of the left and may be accounted as a physiological response to increased work and unlikely to give rise to mechanical strain on the circulation In the majority of cases however the condition is associated with other congenital abnormalities, usually of an obstructive type, in the pulmonary or aortic circuits, and its presence is then of the utmost importance in permitting the establishment of a functional readjustment of the abnormal blood-flow In such instances it is obvious that ligation of the ductus arteriosus would constitute a grave threat to the compensatory collateral circulation, a danger which is not lessened by the fact that the detection of additional congenital abnormalities may be very difficult Thus it may be seen, in connexion with the first case that the continuous murmur of ductal origin was replaced later by a rough systolic one in the pulmonary area, thereby indicating the unsuspected co-existence of a stenotic lesion No doubt the lesion was of a minor character, yet the operation was followed by a severe though fortunately temporary uræmia and the incident serves well enough to illustrate what may happen in a more complicated type of case

The connexion between endocarditis and patent ductus arteriosus is undoubted Nevertheless, it may be questioned whether ligation can have any good effect either preventively or curatively, as the underlying predisposition to infection must be based on the anomaly of anatomical structure rather than irregular circulatory flow and the operation will not alter that factor As a curative measure the value of the operation is still problematical, since the vegetations in general are limited to the ductus and the underlying st defect in the wall of the pulmonary artery is not Indeed, the only practical accomplishment a would be a reduction in the number of systemic these were present, to the ill vantage of the circuit which would thereby receive the full co Recovery from infective endocarditis is not even before the days of sulphonamide treatment, there is no means of ascertaining in the two cases cribed whether the operation in any way influenced th course of the disease as both patients were afebrile and the road to recovery before it was carried out It be that there is a case for ligation of the patent duct arteriosus, if there is, it would not appear to lie in class of patients, comprising the majority, associated with other congenital cardiac defects or in any after th onset of infection In the remainder, a logical indication for ligation might be as a prophylactic measure, but, in view of the natural repugnance of the healthy person to undergo "ideal" operations, particularly major one, it is possible that opportunities to assess its real value will be few

CALCIUM STUDIES IN NORMAL PEOPLE

SIR,—I have been reading Dr Robertson's articles with great interest He quotes figures from balance experiments conducted on normal subjects which showed that below a certain level of Ca intake the Ca output was restricted—i e, the Ca was used more economically In the cases he quotes, the subjects had been on the low Ca intake for only short periods We found the same in indigent subjects who had been on a low Ca intake for long periods (Owen, E C, Irving, J D and Lyall, A *Acta med scand* 1940, 103, 235) So efficient had the utilisation of Ca by these subjects become, that some of them were in equilibrium on intakes as low as 0 25 g Ca per day It would appear from this and other work (i e, Rottensten, K V *Biochem J* 1938, 32, 1285) that one cannot define a *normal* level of Ca intake in this way since the requirements for equilibrium will depend solely on the Ca reserves of the individual under test; and these in their turn depend on the previous dietary Ca history This has recently been stressed by Steggerda and Mitchell (*J Nutrit* 1941, 21, 577) Thus it has been found that Chinese (Kung, L C and Yeh, H L *Chin J Physiol* 1937, 12, 139) and negroes (Kelly, F C and Henderson, J M *J Hyg Camb* 1930, 29, 418) appear to have a lower requirement for Ca than do white people This lower requirement is certainly not racial in origin but is due to the fact that these peoples habitually subsist at lower levels of Ca intake (Kung and Yeh) It therefore seems to me that one cannot quote figures for normal Ca requirements on the basis of balance experiments since the requirement for equilibrium depends entirely on the previous dietary history of the individual The only assessment of adequate Ca intake must be an empirical one—one which keeps the individual in optimal health

"WAR-TIME HEALTH AND DEMOCRACY"

SIR,—May I take up two points in your generous review of my small book in THE LANCET of Nov 1 Lord Hewart's definition of democracy is "a system of government based on the Rule of Law and the Sovereignty of Parliament" your reviewer has telescoped the sentence in my book which gave the definition and the result is hardly fair to the distinguished author of "The New Despotism" Your reviewer gives one or two selected quotations to support his argument that I have "a somewhat introverted view of the doctor in a democracy" Two more quotations, if you will allow me to give them cast doubt on your reviewer's interpretation "My own opinion is that . . . the doctor, *in relation to his professional work*, should steer clear of politics" (Italics mine) "And the individual doctor can always express his political views as a *private citizen* with the right to vote for his man in a free country" (Italics mine again)

London, W C 1 HUGH CLEGG

PLUMP TYPE OF GRAVES'S DISEASE

SIR —In commenting on our paper of Sept 20 Mr Keynes makes the rather surprising statement that " it is dangerous to make any attempt to separate off any particular category [of Graves s disease] as being fundamentally different from the rest ' Mr Rundle in your issue of Oct 25 appears to support this view The cases we described had one distinctive character uncommon in Graves's disease—a tendency to increase in weight while still untreated and actively thyrotoxic In addition they were all young women of about the same age with an unusual degree of lymphatic hypertrophy even for Graves s disease. and five out of eight had amenorrhœa. It seemed to us that these cases formed a distinctive group, though we admitted the existence of transitional types and we suggested that they were displaying an unusual resistance to the thyrotoxic process Since the results of thyroidectomy had not been so satisfactory as we had come to expect in the usual type of Graves s disease, we ventured to suggest that in such cases conservative treatment might be given a trial We presume that it is this mild suggestion which has so alarmed Mr Keynes

Mr Keynes has also made much of the two deaths in this group We did not of course draw any far-reaching conclusions from these deaths they were never a major point in our discussion on this group and it will not surprise us if further experience shows the mortality to be not unduly high None of the surviving cases, however could be classed as good results, and three of them were early recurrences

Later Mr Keynes himself braves the dangers of subdivision sufficiently to admit the existence of ' atypical " categories of Graves s disease, among which he classes the plump type This surely is an odd method of classification, for he presumably groups together all cases which happen to lack one or more of the chief characters of the disease We can see little in common, for instance, between the plump type (which are severe and outspoken examples of Graves s disease in young women) and the type common in the elderly in which auricular fibrillation is the only prominent feature of the disease Yet Mr Keynes would apparently class *these groups together* as " atypical ' categories Of this oddly assorted group Mr Keynes says that " there is room for judgment in forming an opinion for or against operation " *because the* results of thyroidectomy are less dramatic than in the classical type Whether this is a correct statement of the prognosis of this remarkable hotch-potch it is impossible to say , but the statement is interesting as revealing that even Mr Keynes considers the results of thyroidectomy to be not always exactly predictable If this is so, is it so very dangerous to inquire whether there are not in fact different types of the *disease, which may* respond characteristically to treatment ?

To avoid further confusion the conclusions arrived at in our paper were the result of careful observation over a number of years of a series of cases of Graves's disease operated on by the senior surgical staff at a general hospital Mr Rundle's reference to " a surgeon s early efforts at thyroidectomy " is therefore irrelevant

GRADUATION AT AN EARLIER AGE

SIR,—Many will agree with Dr Spencer Paterson, who pleads for graduation at an earlier age in your issue of Oct. 25, when he states that the years from sixteen to eighteen are not very usefully employed But surely the chief reasons are not, as he suggests that students are either learning subjects which they must later re-learn at the university, or are learning classics , because, at the age of seventeen, the great majority are already working for their first M B Rather these years are not usefully employed because the work must conform strictly to a university syllabus which demands an unnecessary amount of detail, and does nothing to encourage a general or scientific background. Added to this, in many cases are the unnatural restrictions to freedom and independence imposed at this stage by the public-school system

To justify his plea Dr Paterson also referred to the undesirability of late marriages and small families among the medical profession This is found in the professional classes as a whole and the reasons are largely economic. For this the state is responsible. and the state must find the cure not the university or the medical authorities to whom the plea was directed And let us note that the one state that has tackled this problem provides medical men even in their student days, with an adequate salary I cannot help feeling that the moral breakdowns in medical students which Dr Paterson is apparently called on to treat may be due not so much to frustration with the medical curriculum as to the realisation that at the age of twenty-one they are still and for the next few years will remain just as dependent on their parents for their every need as they always have been

I submit Sir, that our efforts would be better directed towards changes in the medical curriculum and in the status of the young doctor than towards graduation at an earlier age Superficially this suggestion may appear as a panacea for the ills to which Dr Paterson so rightly pointed. But perusal of your number (Aug 30) devoted to medical education will show that in this country graduation probably takes place already at an earlier age than in any country in the world with the exception of Nazi Germany

THE HEN AS MIDDLEMAN

SIR —I *welcome the criticism that appeared in your* issue of Oct 25 (p 487) on my article in *Nature* although the suggestion that being an authority on poultry. I naturally defended the animal of my choice from the obloquy cast on it by agriculturists and dietitians is not too happily phrased since the casual reader may assume that I wrote the article from reasons of self-interest rather than from the point of view of the welfare of the nation In my article I contended that on dietetic grounds, the egg is just as essential an article of diet as milk. and that from the point of view of economy of conversion of feeding-stuff protein to human food protein the hen has a claim to priority second only to the dairy cow I assume that this dietetic part of my contention is accepted But you attempt to destroy my case for the hen on economic grounds Not being an economist I am at a disadvantage but even to my amateur mind the arguments adduced appear a little unsound To base an argument on the relative price the Government is prepared to pay for the protein in eggs and milk in these days of price regulation and to argue that such prices reflect the relative efficiencies of the dairy cow and the hen to produce such protein is surely illogical, apart from the fact that I have never suggested that egg production should be encouraged at the expense of milk production The present prices paid to the producer by the Government are admittedly fixed in relation to cost of production but such costs cover many other factors than that of relative efficiency of food conversion The relatively high prices paid for eggs are essentially due to the fact that Government action has resulted in poultry producers having to cut their flocks below the normal economic level whereas no such action has been enforced in the case of the dairy farmer The price argument works both ways Following the same line of argument I could with equal justice maintain that the Government by asking the consumer to pay 2½*d* for an egg containing 6–7 g of first-class protein as compared with a pint of milk at 4½*d* containing 18 g is of the opinion that egg protein is much more valuable to the consumer, weight for weight than milk protein

The contention that the hen being a much smaller animal than the dairy cow requires much more energy for maintenance than the dairy cow weight for weight is an accepted fact but even here there is a possible fallacy in the argument since the relative cost of maintenance when charged against the finished product will vary according to the relative amounts of the finished product produced It is of interest to note that a 5 lb hen laying 140 eggs a year produces 78% of her body-weight in the form of dry human food (not counting shell) whereas the 1250 lb cow giving 600 gallons of milk produces only 59% of her body-weight in the form of dry human food Finally, although the energy requirement for maintenance is correlated with body surface rather than body-weight, such is not the case with protein There is, consequently, no reason to assume that a small animal is less efficient as a converter of protein than a large animal

I am not convinced that the reasoning in my *Nature* article is at fault If need for protein is of primary importance to the nation, then the hen deserves first consideration next to the dairy cow If, on the other hand, energy requirement is the primary need, then the pig should rank next to the dairy cow

CANCER AND OILING OF FLOORS

SIR,—As the suggested method of oiling floors has, I think been in use at certain schools for very many years, without any detriment to the health of a few generations, it would appear that the method is harmless One is thankful for assurance on the new suggestion of oiling blankets

Market Drayton PETER W EDWARDS

PROPHYLAXIS AND TREATMENT OF COLDS

SIR,—In his article of Nov 1 (p 534) Dr Thrower mentions experments carried out for controlling colds by ultraviolet light and states that the results were disappointing This is by no means the experience of observers who have used ultraviolet irradiation for many years in this and other countries The common cold can be aborted in a large percentage of cases if proper technique is adopted and suitable apparatus is used The nostrils and pharynx can be sterilised by application of ultraviolet rays by means of quartz applicators attached to the Kromayer mercury-vapour lamp first used in Berlin in 1903 This treatment should be combined with infrared irradiation applied over the antra and general U V irradiation to increase the bactericidal power of the blood-stream Apparatus has unfortunately not been standardised in this country, the result being that innumerable pieces of apparatus now in use have but little therapeutic effect In addition the technique adopted to carry out experimental investigations is often faulty

Wimpole Street, W 1 W ANNANDALE TROUP

TOWARDS A NATIONAL SERVICE IN CLINICAL PATHOLOGY

SIR,—After reading Dr Dyke's article of Oct 25 doctors in general will be looking forward to the time when the scheme envisaged will have become an integral part of the practice of medicine in this country It may, however, be of interest to Dr Dyke and others to know that a comprehensive pathological service very much on the lines indicated has been functioning in at least one part of the country for many years, and that consequently one or two statements in this excellent article are not strictly correct

More than a quarter of a century ago the Kent county council established a laboratory for carrying out public-health pathology It soon became evident, however, that the line of demarcation between public-health pathology and clinical pathology was very indistinct, and it seemed desirable to extend the service to provide facilities for undertaking pathological work for all doctors practising in the county The development of the scheme was very rapid, and even before the war nearly 100,000 specimens were being examined annually , about 30,000 in the six branch laboratories at the county hospitals and institutions and the remainder at the central laboratory at Maidstone Briefly, the scheme as it operates at present is that medical officers of health, general practitioners and the medical staff of hospitals in the county which have no pathologist on the staff may send into the main laboratory an unlimited number of specimens for examination Field work for the purpose of investigating and controlling the spread of epidemic disease is undertaken by the pathologists in collaboration with the district medical officers of health In the case of patients residing within a reasonable distance of Maidstone, and who are able to travel, the doctors may wish to have specimens collected in the laboratory , in some cases, of course, this is necessary, and is greatly appreciated when such investigations as glucose-tolerance curves and urea-clearance tests are required Furthermore, the services of pathologists are available to assist in consultation with doctors in the investigation of clinical problems at the bedside of their patients These services are entirely free of charge to the doctor and the patient , outfits for the transmission of specimens are also supplied free, and the only expense incurred is that of sending the specimens to the laboratory The cost of the laboratory is a charge on the county rate and is relatively small for the services provided

It is not claimed that this pathological service is by any means ideal, and plans for future developments along present lines have been made , but that there is ample need for such a service is evidenced by the general appreciation expressed of the value of the provisions already made in this county

Maidstone CONSTANT PONDER

FIRST-AID IN WAR-TIME

SIR,—I was interested to read Dr Hodgson's letter in your issue of Oct 25 During the past year the Halifax casualty services have been instructed with special reference to shock , hæmorrhage , wounds , burns , certain fractures , war-time neuroses , the speedy evacuation of casualties , the diagnosis as between F A post and hospital casualties , and the movement, parking and spacing of casualty vehicles In addition, a thorough knowledge of local geography (helped by night exercises) is part of their curriculum We have cut out all elaborate bandaging and splinting at incidents Tourniquet dangers are stressed I am of the opinion that a simple textbook on war-time first-aid would be appreciated by the casualty services

G C F ROE
Medical Officer of Health, Halifax

Q CAMP

SIR,—In your review of W. D Wills's book "The Hawkspur Experiment" (Oct 18, p 474) the principles on which the Q Camp was run are summarised in a way which shows a deep understanding of our work, but there is one correction I should like to make The numbers never reached 70, nor could we have carried on the methods with so many at a time We considered about 30 to be a desirable maximum, although had the demand been pressing we might have been willing to exceed this, but certainly not to go beyond 50 This does not imply that Q Camp methods are unsuitable for such institutions as Borstals or prisons, where large groups are at present the rule Rather does it mean that large groups are unsuitable for the reformative work they aim to do The combination of individual study and individual help with experiments in community living, which seems to be the lines most hopeful for the re-education of offenders, requires that these larger groups be subdivided

MARJORIE E FRANKLIN,
Oxford Hon Secretary, Q Camps

HOME GUARD TERMINOLOGY

SIR,—We are discussing what title should be given to the minor aid-posts set up by the Home Guard and provided by the authorities with a minimal equipment I am told that in one area these posts, which do not differ in any essential, are to have no less than three sets of initials according to whether they are associated with battalion headquarters, companies or platoons The initials proposed are H G B A P , H G C A P and H G P A P The prefix H G is necessary because the army authorities already use C A P and P A P , as was pointed out by one of your correspondents

Surely it is time that we called a halt to this multiplicity of initials and gave first place to brevity and accurate description Our Home Guard posts would be called points by the civil authority and by this term they intend to signify that the amount of assistance which can there be given is very much less than that provided at any post The word point is not felicitous because the initial "P" may equally stand for post or party but it does at least indicate an important distinction which is missed by those who would use the expression aid-post for every sort of place at which medical attention is available I must admit considerable sympathy with those who use the expression C C P (casualty collecting post) as both descriptive and distinguishing for all Home Guard posts and would venture to hope that official authority may be given for the use of this term before a riot of uneasy nomenclature submerges us BATTALION M O

WAR-TIME NURSERIES DISCUSSED

A STRANGE situation has arisen: everyone agrees that if women are to go into industry in large numbers their children below school age must be cared for, preferably in nursery schools and day nurseries; the Government has endorsed this view so strongly that local authorities can claim the entire cost of starting nurseries; and yet, after two years of war, there are at present only 163 day nurseries in the whole country, receiving between them barely 6000 children—and there are more children than that between 2 and 5 in many a county borough. Reasons for this curious inertia were discussed at a conference on Oct. 29, arranged for London and the Home Counties by the Nursery School Association of Great Britain and the National Society of Day Nurseries, with Lord Horder presiding. Administrative control has been given to the Ministry of Health; and, though approval of every new scheme for a nursery must be obtained from the Board of Education as well as the Ministry, power to give such approval has been delegated to the senior regional officers and to inspectors of schools, and arrangements have been made so that both approvals can be obtained at the same time. Difficulties in finding premises, staff and equipment are the chief delaying factors, but there are also wide divergencies in the enthusiasm with which local authorities approach the idea of establishing nurseries.

Mr. J. C. WRIGLEY (Ministry of Health) reminded the conference that in the early days of the war the need for nursery schools or residential nurseries had been mainly in the reception areas; now the need was chiefly in centres of industry where women were being increasingly employed. He suggested that whenever a nursery was planned local authorities should draw up a time-table fixing the dates on which the nursery should be approved, equipped and opened, and should make someone responsible for seeing that this time-table was kept. This dovetailed with a suggestion from Lady ALLEN OF HURTWOOD, one of the chief movers of the conference, that the Ministry of Health should appoint some dynamic person to apply ministerial policy and coordinate the departments, authorities and groups concerned with the needs of the young child. She felt that nurseries for babies under 2 should be established only with the greatest reluctance. She was doubtless thinking of the dangers of infection, so great among children of this age when they are gathered together; it is well to hesitate, especially if they are to be housed in the same nurseries as the 2–5 group. On the other hand it is not feasible to establish separate nurseries for those under 2. The mother with a sizeable family cannot be expected to get the bigger ones ready for school and then go round disposing of the younger ones at two different nurseries before she goes to work at 8 o'clock. Miss FLORENCE HORSBRUGH, parliamentary secretary to the Ministry of Health, said that in the ordinary way it was questionable whether the mothers with babies under 2 should be going to work at all, but just now mothers could look after their children best by making munitions to defend them. But she was not wedded to the notion that the only way to get the children looked after was in nurseries. A nursery, she pointed out, would take about 40 children; if something like 400,000 women with children under 5 were going into industry during the next few months we should need 10,000 nurseries straight away. It was impracticable to establish them on that scale, and she felt we must call upon a home guard of women—grannies and aunts—to do some of the minding while the younger women went into the factories. This laid Miss Horsbrugh open to the charge of being "minder-minded." Many people feel that there are strong objections, in the usual way, to this haphazard method of child care, and that nurture is best ensured in the nursery school. Yet it is doubtful whether finality lies on either side of this fence; MARGUERITE DOBBING, in a letter in the *New Statesman* of Nov. 1, tells of her own complete conversion from one opinion to the opposite after working in an evacuated residential nursery school for 21 months. The children there in spite of expert care seem to be going backward instead of forward, reverting to thumbsucking and temper displays; and this is due, she thinks, to lack of personal love. The aunt and granny could possibly achieve more in this direction than the best nursery school, however far they fell short in other ways.

This was borne out to some extent by the remarks of Miss ANNA FREUD at the conference. Nursery schools, she said, had never been meant as a substitute for the home, any more than the welfare clinics did away with the need for the mother's care, or child-guidance clinics with the need for education by the parents. All these services were simply extensions of the home. At present, however, families are dissolved, homes hardly recognisable and children scattered in billets. The nursery schools are confronted with the task of filling all the gaps, and they have done their best. But the mother-child relationship is normally a 24-hour affair, and the child who goes back and forth between home and nursery may in the end feel a stranger in both. Miss Freud believed in making every possible effort to include the real mothers in the life of the nursery. Some people, she felt, looked on love from the parents as a luxury which a child could not expect to get in war-time. In the last war the same remark was applied to things like sugar, fresh fruit and butter, of which continental children were deprived; these were now recognised as necessities. Today psychologists knew that there were some types of maladjustment in later life which were rooted in the lack of an ordinary home life in the first five years.

THE RIGHT STAFF

Miss FREDA HAWTREY made constructive proposals for dealing with the time lag in the development of nurseries due to lack of staff. The two types of women called on to fill responsible posts, as she pointed out, are hospital nurses and nursery school teachers. They have had totally different types of training and are therefore good at different things. Thus the nurse is (regrettably) used to residence and long hours. She is accustomed to handling babies under 2, to routine, to preventive measures against infection, and to detecting signs of illness early; but she has usually dealt more with sick children than healthy ones. The nursery school teacher is used to handling large groups of young children, believes more in free activity than routine, and has her attention focused on health; but she takes no responsibility for children under 2. Thus a hospital nurse is more suited for charge of a nursery which admits children of all ages under 5 and a nursery school teacher for a nursery which takes children between 2 and 5. In all nurseries where there are more than 20 children between the ages of 2 and 5 a nursery school teacher can be added to the staff; but cooperation between the nurse in charge and the teacher is not always easy. To overcome this difficulty, induced by the differences in training, courses in child management are being arranged for nurses, Miss Hawtrey said, by the Royal College of Nursing and for nursery school teachers by the Board of Education. The audience did not rise as one woman—as might have been expected—and say "But why not courses for both together?" Surely no better opportunity could be wished for establishing an understanding between the two groups of workers; and clever teachers should be able to help each student to merge her professional bias in the aims of the job she is going to do.

Miss Hawtrey suggested that the few available trained women—whether nurses or teachers—should be put into the key posts, and that the minor posts should be filled by "nursery nurses" trained to look after children in private families, by auxiliary nursery assistants who might be recruited from among young mothers, nannies, friendly aliens and elderly women. These could register with the Women's Voluntary Service and take a short training course with the Child Care Reserve. She would like to see emergency training centres started in connexion with existing nurseries, and estimated that if 24 students each took a 6 weeks' course, one centre could provide nearly 200 nursery assistants in a year.

PAYMENT FOR CARE

The cost to the mother of leaving her child at a day nursery was not discussed at the meeting, but this may well have an important bearing on the extent to which the nurseries are used when they are set up. The standard charge suggested by the Ministry is 1*s.* a day for each child and though this is little enough in return for all the child enjoys it is a formidable sum for a woman who happens to be working 7 days a week in return for a wage ranging from £1 18*s.* to £2 10*s.* a week. Cases of hardship can be considered and if necessary the payment can be reduced, but women in industry might well be granted this relief free of charge It would pay well as a national investment in healthy child life

---

Obituary

RALPH MORTON CALDER

M B GLASG , SURGEON LIEUTENANT, R N V R

THE death has been reported of Surgeon Lieutenant Ralph Calder, who was posted as "missing presumed killed" last August He was born in 1913, the only child of Mrs Janet Calder of Ayr, and educated at the Academy there He graduated M B with commendation from Glasgow University in 1935 He held house-appointments at Ayr County Hospital and the Glasgow Royal Hospital for Sick Children, and he was Prof T K Munro's last house-physician at the Glasgow Western Infirmary before his retirement It was during this time that Calder first showed his aptitude for experimental work, though his one great desire was to be a physician But he was persuaded for a time at least to study pathology, and after two voyages as ship's surgeon he was awarded in 1936 an M R C scholarship in experimental pathology He chose as his subject liver necrosis and cirrhosis and began work at the infirmary under Professor Blacklock, who has written of him

"Calder was a stimulating laboratory colleague He approached any difficult pathological problem with a critical mind, but his criticism was always constructive and he dearly loved planning experiments to solve it These experiments, as his work on the liver proves, were always logical and were planned to have a bearing on the elucidation of disease in the human subject He did not neglect the purely morbid anatomical side of pathology and in the little teaching which he did he could draw an admiring group of students around him while he explained the nature of the lesions present Then from his clinical knowledge he would correlate in a most lucid manner the postmortem and clinical findings His academic accomplishments were great for one of his years, yet he was always modest and helpful towards his less gifted brothers and respectful of his seniors, who foresaw a great career in store for him and by whom he will be greatly missed"

In 1938 Calder was awarded a Graham scholarship and he came to London to continue his work on the liver under Professor Cameron at University College He later submitted the results of these investigations as his M D thesis He had joined the R N V R at the beginning of 1938 and he was called up before the outbreak of war For a year he carried out the routine work of a medical officer attached to a general hospital, till he was detailed to specialised research work At his own request he was later posted to a ship and on this service met his death His published work included a report of a case of cold allergy and a study of autoplastic splenic grafts His opinions were clear and his criticisms penetrating, but if he had forthrightness he also had charm, and his friends will remember him as an interesting and stimulating companion with a wide knowledge of literature and a deep love for the music of Mozart and Handel

GEORGE ALEXANDER COHEN

M B EDIN

MANY who attended the court of the coroner for Eastern Middlesex during the last fifteen years will regret the death of Dr George Cohen on Oct 16 at the age of 71 Dr Cohen who was born in Hull qualified in 1893 at Edinburgh University, and after postgraduate study at St Bartholomew's and Dublin, he saw a good deal of service abroad as a ship's surgeon He set up in general practice at Harringay in 1906 but forensic medicine was his real bent He was called to the by the Middle Temple and in 1910 appointed for the then central Middlesex district In 1926 A M M Forbes, coroner for the eastern division of county, died, and the eastern division absorbed the under Dr Cohen After the Coroner's Act 1926 became law, his jurisdiction was widened by the accretion of the parishes of Edmo Southgate and Enfield In his younger days he was noted instructor in ambulance work and a captain in Volunteer Brigade of the Middlesex Regiment For ov six years he represented the Tottenham-Division on the Middlesex county council, but resigned on his appointment as coroner

ROBERT WALLACE NESBITT

M B DUBL , F R C P I , SURGEON COMMANDER, R N

Commander Robert Nesbitt, who lost his life throu enemy action in September, began his medical care in 1912, when he entered Trinity College, Dublin, wi distinction as a junior exhibitioner—a standard maintained throughout his student days In 1915 joined the R A M C as a private, but was sent back t same year to complete his medical studies He qualifie L Med as quickly as possible and in 1918 joined the Nav as a temporary surgeon After the war he elected t stay in the service, returning to Dublin to take his M degree in 1923 He had a distinguished service recor holding the appointment of medical specialist at Hasla Plymouth and Chatham Much of his leisure was spen on postgraduate work and a careful study of the literatur of his special interest—diseases of the chest But h found time to write several plays, one of which was acte by the Dublin Abbey Theatre He loved a good argu ment, and his friends enjoyed the charm, humour an eloquence with which he disposed of their points A wel turned phrase or subtly expressed thought gave him in tense pleasure, for he had the gentleness, sympathy an understanding of a poet

Births, Marriages and Deaths

BIRTHS

BARBER—On Oct 30, at Dunmow, the wife of Dr Geoffrey Barber—a son

CALVERT—On Oct 31, at Barrington, Cambs, the wife of Dr Henry Calvert—a daughter

CAREY—On Oct 31, at Sherborne Dorset, the wife of Surgeo Lieutenant Fraser Carey, R N V R—a son

DAWSON—On Oct 22, at Oxford, the wife of Major J R Dawson R A M C—a daughter

GRANT—On Oct 30, at Farnham, the wife of Captain Russel Grant, R A M C—a son

HELLIER—On Oct 21, the wife of Dr F F Hellier, of Par Square, Leeds—a son

RICHARDS—On Oct 30, at Sutton, the wife of Captain A H Mordaunt Richards, R A M C—a son

SIDEY—On Oct 31 at Aberdeen, the wife of Surgeon Lieutenan J D Sidey, R N V R—a daughter

DEATHS

COLLIE—On Oct 27, at Bournemouth, Frank Lang Collie M D Aberd, aged 77

MARTLEY—On Nov 2, Francis Charles Martley, M D Camb F R C P I, D P H

PENFOLD—On Oct 27, at Melbourne, William James Penfold M B Edin, B Hy Durh, D P H, director of the Baker an Shaw Institute, Alfred Hospital, Melbourne

PICTON PHILLIPS—On Oct 29, William Edward Picton Phillips M R C S, of Egerton Gardens, S W 3

TIDEY—On Oct 29, at Winchester, Stuart Alexander Tidey M D Lond, M R C P, aged 84

WALKER—On Oct 30, at Guildford, John Morris Walker M B Glasg

WATSON—On Oct 25, Thomas Boswall Watson, M D Edin late o Woldingham Surrey

WATSON—On Nov 1, Henry Allan Watson, M B Glasg, o Worcester, aged 70

AMERICAN DOCTORS FOR BRITAIN—Up to Sept 4 th number of doctors in the United States who had applie to enrol in the R A M C was 230 (*J Amer med Ass* Sept 13, 1941, p 941) Of these 138 were unsuitable fo various reasons, 42 of the remainder had actuall received passports

Medical News

al College of Physicians of London

t a meeting of the college held on Oct 30, with Sir Charles son the president, in the chair, Sir Wilson Jameson, Dr Spence and Dr W A Daley were elected councillors following were re elected representatives of the college Adolphe Abrahams on the committee of management of conjoint board, Sir Comyns Berkeley on the council of Central Midwives Board, Dr John Hay on the court of ernors of Liverpool University, and Sir Stanley Wood- k on the Central Council for District Nursing Dr Cyril ood was elected a member of the library committee

he president announced the appointment of Sir Wilson neson as Harveian orator, and Surgeon Captain Macdonald tchley as Bradshaw Lecturer for 1942, and the award of Jenks scholarship to Terence Robert Lancelot Finnegan, of Epsom College

he following having satisfied the censors' board were ted members —

Margaret D Baber, M D Lond, W W Brigden, M B Camb, A Burt, M B Camb, D L Caldwell, M.B Camb, G W M idlay, M D Edin G M FitzGerald M B N U I, Geoffrey well, F R C S G S Graveson M B Camb, Ursula James M B nd., Joseph Marks, M B Lond Thomas Parkinson, M D Lond, T G Prunty, M B Camb, and I B Sneddon, M B Sheff, geon lieutenant, R.N V R

Licences to practise were conferred upon the following 159 ndidates (138 men and 21 women) who have passed the al examination of the conjoint board —

Hazley Anderson, R H Andrews, I J Anrep, C D Baker, azem Barrada Edward Barry Smith, A W Bauer, Peter Baxter, einrich Beck Marcel Bednar, C J A Bell, J A R Bickford, argaret A Billinghurst, D A Blacketer Simmonds, Joseph orrowdale, D S Boyle S V Brookes, Jean L Broughton, R J D rowne C J Bruhn J D Bruzaud Olive N Bywaters, D A Carnegie D W F Charlton, W H Chase, J F Childs N F larke B U Coffey, H I Coombs, R A Craig, A F Crick, M C ross, F X Darne R G Dewhurst L W D Drabble, F M P ckstein J R Ellis, Shifra Ernst A T G Evans A J Evans, J S Evans J W G Evans J H W Fagan T N Fison, J M itton A W H Foxell Beryl M Givan E C E Golden Gertrude oldscheider, J G Goodhart, A J R Gottfried J D C Gowans, G Green B P Griffin H J Hagger, C L Hall, Doris N Hall, onstance M Hallett, J H G Halliday, Penelope K Hammick, E F Hammond P A S Hargrove, Charles Harris, R J Harvey, Thomas Haw Ursula M Hickman, A W Hind, S J Hinds W K H L Hoffmann, A E Howarth, D R Hughes Isabella C F Hungerford Menahem Icht, E B Jarrett, Rees Jenkins, C H Jones, G Jones K C D Jones Samuel Jung, F L King-Lewis F M ancaster, Richard Leigh, K H Lim, W K. Diplomas in child health were granted, jointly with the Royal College of Surgeons, to the candidates named in our issue of Oct 18 (p 473), and diplomas in public health to L C Lodha, L G Norman and M A G Ward

Royal College of Obstetricians and Gynæcologists

At a meeting of the council of the college held on Oct 25, with Prof W Fletcher Shaw, the president, in the chair, the following were admitted to the membership —

Gavin Boyd Glasgow Edward Gledhill Batley R M Millen, London Constance E Peaker Leeds Kathleen M Robinson, London, Katharine C Rogers London R X Sands, London, Violet E A Sykes London, and George Wynn-Williams London

The following have satisfied the examiners for the diploma

Elizabeth G W Barker, Constance L Beynon L A Cruttenden, Dorothy Cunningham R G Denniss, A A Fyffe R P Gammie, Jean L Hallum L W Hefferman, Geoffrey Hollingsworth Hilda E McNamara P S Norris Jean F Thompson, H B Watson, Eva M M Willett, and H G Wolskel

Association of Anæsthetists of Great Britain and Ireland

The following have been elected officers of this society for the coming year president, Lieut Colonel Ashley Daly, R.A.M C, vice-president, Dr C F Hadfield, treasurer, Dr Z Mennell, and secretary, Dr A D Marston

National University of Ireland

The Dr Coffey travelling studentship in physiology has been awarded to Dr J W Harman and the bursary in medicine to Dr John McSorley

North Western Tuberculosis Society

A meeting of this society will be held on Thursday, Nov 13, at 3 P M., at 352, Oxford Road, Manchester Dr G H. Leigh, the president, will speak on facts and fancies and the tuberculosis death-rate

British Institute of Philosophy

On Friday, Nov 14, at 3 P M., Prof. Herbert Dingle, D Sc, will speak at University Hall, 14 Gordon Square, London, W C 1, on the universe in relation to modern physics Cards of admission may be obtained from the director of studies at University Hall

Royal Institution

On Tuesdays, Nov 25, Dec 2, 9 and 16, at 2 30 P M Prof J C Drummond, D Sc, will lecture on recent advances in the science of nutrition and their significance in war-time The meetings will be held at the institution, 2, Albemarle Street, London, W 1

Pharmaceutical Society of Great Britain

A meeting of this society will be held at 17, Bloomsbury Square, London, W C 1, on Thursday, Nov 13, at 2 30 P M, when the Hanbury medal will be presented to Mr Harold King, F R S, a member of the staff of the National Institute for Medical Research Dr King will afterwards speak on chemistry and pharmacy

Royal Society of Medicine

On Tuesday, Nov 11, at 2 30 P M, there will be a discussion in the section of therapeutics and pharmacology on the kidney and hypertension The openers will be Prof Arthur Ellis, Dr Clifford Wilson, Prof G W Pickering and Dr Robert Platt The clinical section will meet at St Mary's Hospital, Paddington, at 2 15 P M., on Nov 14 At 3 30 P M on the same day Prof A J Ballantyne will read a paper on angiomatosis of the retina to the section of ophthalmology The section of neurology will hold a clinical and pathological meeting on Nov 15, at 10 30 A M, at Chase Farm Hospital, The Ridgeway Enfield, Middlesex

L C C Vitamin Tests

The London County Council has arranged for tests on the effect of American vitamin capsules to be carried out on 500 elementary school children, subject to the consent of their parents One vitamin capsule a day will be given on five days a week for nine months to 125 children selected at random in a reception area and to 300–400 children similarly selected from those attending elementary school in London An equal number of children will be chosen as controls who will be given capsules with a harmless inactive content

Hostels for Old Age Pensioners

At a meeting of the old people's welfare committee of the National Council of Social Welfare on Oct 31, Lord Soulbury, chairman of the Assistance Board, announced that where pensioners did not need continuous medical attention or nursing but needed to have such care at hand the board would make their pension sufficient to enable voluntary organisations to maintain hostels for them To this end the supplementary pension would be made sufficient to provide the pensioner with an income of 30*s* a week.

Medical Aid for China

During their second year's work the China Medical Aid Committee were able to send Dr Kent, an Austrian surgeon, and Dr Coutelle, a German physician and physiologist, to China and in November, 1940, they were posted to Red Cross units in Hunan-Hupeh areas Dr Rosa Coutelle and Mrs Maria Kent, a trained nurse, set out to join their husbands in March but owing to enemy action had to return to England There are now nineteen foreign doctors working in the Red Cross units under Dr Lim The units consist of a few trained Chinese first-aid workers and an interpreter The doctors treat the sick and wounded, perform simple operations, treat fractures, teach hygiene and sanitation, and sort out the wounded to be sent to the base hospital 200 miles away The press appeal made by the committee in July (*Lancet*, July 5, p 24) raised £400 and further donations will be welcomed by the treasurer, Dr E H T Hambly, Treharrock, Seer Green, Bucks

Prisoners of War

W S /Captain J B Sherman, M B Melb, R A M C, and W S /Captain I R I MacDonald, M B Edin, R A M C, have been posted as prisoners of war

Paddington Medical Society

A meeting of this society will be held at 3 45 P M, on Nov. 11, at St Mary's Hospital, when there will be a discussion on how to solve the night call problem in London

Chadwick Lecture

Mr Frederick Hiorns, F R I B A, will give a Chadwick lecture on Tuesday, Nov 11, at 2 30 P M, at the London School of Hygiene, Keppel Street, W C 1 He will speak on hygiene technique in building, or the economic, psychological and health aspects of surface treatment

Royal Faculty of Physicians and Surgeons of Glasgow

At the annual meeting of the faculty the following were elected office bearers for the ensuing year —president, Mr Roy Young, visitor, Mr James MacDonald, treasurer, Mr William Richard, librarian, Dr W R Snodgrass, other councillors Mr J Scouler Buchanan, Mr Donald Duff, Dr John Gardner, Dr Stanley Graham, Dr John Henderson, Mr J A C Macewen, Dr Donald McIntyre, Dr Noah Morris, Mr William A Sewell, and Mr J Forbes Webster

Alliance of Hospital Administrators

The councils of the Incorporated Association of Hospital Officers (which has hitherto limited its membership to the administrative staffs of voluntary hospitals) and the Incorporated Association of Clerks and Stewards of Mental Hospitals have recommended the fusion of their societies The new body will open its membership to administrative officers of local authority and other hospitals, and a committee will be set up to consider the recruitment and training of administrative hospital staff

Notes, Comments and Abstracts

TO RADIUM SMALLHOLDERS

In addition to the radium held by hospitals under arrangement with the Radium Commission and King Edward's Hospital Fund there is an appreciable amount in the possession of small hospitals, medical practitioners and commercial firms, and the Minister of Health has now issued a pamphlet instructing these users how to protect their supplies All radium exceeding 1 mg in amount should, when not in use, be kept in a bore-hole or steel container of an approved type described in the pamphlet The bore-hole advised is 50 ft deep, and otherwise similar to that lately described by Lederman and Mayneord (*Lancet*, 1941, 2, 461) The container consists of a round or square block of mild steel with a narrow opening leading to a cavity in the centre to hold the radium The opening is closed by a screw plug The walls of the container must be not less than 3 in thick In a hospital in a vulnerable area not more than 350 mg should be in use at any one time Radon should be used instead of radium where possible and the treatment of patients by radium should not continue during an air-raid unless they are in a shelter If a bomb falls where radium is known to be, the medical officer of health should be at once informed He will have the area roped off and notify the Ministry of Health, who will arrange for experts to examine the site

SALAZOPYRIN IN RHEUMATISM

Good results are reported by Svartz,[1] in Stockholm, from the use of a compound of sulphapyridine and salicylic acid in rheumatism She had previously found that though sulphonamides alone were sometimes valuable in septic arthritis they had no effect on the ordinary rheumatic case, but it seemed possible that they might render the responsible organism more sensitive to the action of salicylates Simultaneous medication with sulphonamides and salicylates was therefore tried, but without effect Finally, however, Askelof and Willstædt prepared salicylazosulphapyridine, a preparation which is now produced commercially by Pharmacia of Stockholm under the name Salazopyrin Svartz reports five cases of rheumatic polyarthritis successfully treated with this drug One woman of 33 had had polyarthritis since 1933 and when seen could only walk a few steps difficulty, salazopyrin, 0 5 g four times daily, was begun on Oct 29, 1940, by Jan 31, 1941, movements were almost normal and the patient felt well Another woman of 44 with arthritis of 1½ years' standing, chiefly affecting the knees and metacarpals, was given several courses of salazopyrin amounting in all to 900 tablets of 0 5 g each This lady found herself standing on a chair energetically chasing a moth The other cases reported are similar, except that one developed a toxic rash after treatment for 10 days with 1 g six times daily Svartz also reports four cases of ulcerative colitis in which administration of the drug was followed by complete remission of symptoms Salazopyrin is only slightly soluble in water, but its alkaline salts dissolve fairly well Part of it is excreted unchanged in the urine, causing an orange discoloration if the urine is alkaline It does not give immediate relief of rheumatic pain and it may therefore be necessary to give salicylates with it The dose recommended for adults is 1 g four to six times daily, and treatment can be continued for weeks or months The blood picture should be watched, since mild anæmia was seen in some patients, no serious toxic effects were noted, though the drug had sometimes to be withheld for a time because of a rash

BOOKS FROM THE ARGENTINE

In their new volume on primary malignant tumours of the bronchi and lungs (Buenos Aires Hachette Pp 401), which is the only modern book written in Spanish on this subject, Prof Julio Palacio and Prof Egidio Mazzei describe three new clinical pictures associated with pulmonary growths the osteo-arthropathic, in which hypertrophic osteo-arthropathy is the characteristic sign, the pseudocardiac which produces symptoms resembling angina pectoris, paroxysmal tachycardia or cardiac insufficiency, and a type in which Klumpke-Dejerine paralysis gives a valuable pointer in the diagnosis of carcinoma of the apex of the lungs Several years ago the authors were awarded the Alvarenga prize of the Paris Academy of Medicine for their work on atelectasis of the lung, and in discussing atelectasis caused by bronchial carcinoma they draw attention to two new signs which they have observed deviation of the trachea (palpable in the suprasternal notch) during inspiration, in cases of atelectasis of the superior lobe, and the radiological finding of an unusual degree of translucency in the lung adjoining the atelectic lobe

In his book "Las Neurosis en la Guerra" (Buenos Aires Aniceto López Pp 251) Prof Gregorio Bermann discusses the place of psychology, psychiatry and psychotherapy in the treatment of people affected by war conditions During the Spanish civil war Professor Bermann was chief of the section of neurology and psychiatry at the military hospital at Madrid and his book is based on his own clinical experience Prof Emilio Mira, who spent some months at the Maudsley before taking up a post in South America, has written a foreword to the book

Warner's Calendar of Medical History —Messrs William R Warner & Co did not expect to be able to print further editions of their diary during the war, but they have obtained the authorisation of the paper control to publish a limited number—less than half of last year's edition The calendar is available only to members of the medical profession, and any doctor who is a regular user or who would like a copy for 1942 should write at once to Messrs Warner, Power Road, London, W 14

The fact that goods made of raw materials in short supply owing to war conditions are advertised in this paper should not be taken as an indication that they are necessarily available for export

MEDICINE AND DUTY*

T B LAYTON, D S O, M S LOND.

SURGEON TO THE THROAT AND EAR DEPARTMENT OF GUY'S HOSPITAL, OTOLOGIST TO THE FEVER SERVICE OF THE L C C

THE influence of Nelson s order of the day at Trafalgar has come down to us through more than a century Its various manifestations affect our profession there is the duty of the one and of the many, the duty of the immediate emergency and of the never-ending routine

When a boy and a girl sign on at a medical school they join a profession in which they can no longer call any minute of their future lives their own At any moment they may have to give up whatever they are doing to go and see someone in distress, that is one of the glories of our profession If that distress is grave the doctor may have to collect a team to take action or to hand the patient over to a team which is in readiness These are the aspects of duty in acute disease, and once one is inured it is not very hard to rise to them It is no disparagement of the heroes of Trafalgar to say the same of their response to Nelson's signal, when everyone was on tip-toe for a fight Far harder were the two years before Toulon when duty consisted in seeing that every day every rope and every spar was in its place, and when, for many, that was the whole of duty In the same way we have with chronic disease a communal duty, made up of the personal duty of the many Preventive and social medicine are developing around us Our communal duty is not analogous to the work of a gun-team in the *Victory*, or even to that of her whole ship's company, but rather is comparable with the teamwork of the whole fleet We have our firms at Guy's, the success of each depending on the sense of responsibility and duty of each member of it But often one firm needs the assistance of another, and we have not yet replaced the enthusiastic emulation of competing firms by an equally enthusiastic fusion of firms working together We must do this, and in such a way that for one patient a medical firm may fuse with an orthopædic firm, for another with an ear firm, while for a third all three or more may be needed, and we must see that the patient does not fall between two stools and that there is the same individual attention as there was when the patient was entirely under one man Extend that idea to a similar fusion between different institutions, so that a patient may be at the same time under the care of someone at Guy's and someone else at an L C C hospital nearby and perhaps under others at an L C C hospital in the country or at Guy's-in-the-country, and under still more at a convalescent home or a rehabilitation centre belonging to a regional scheme At present this idea that each of us should work for his patient in a medical world which includes several institutions is little developed, but we have to build a new code and a new etiquette between institutions

DESTINY AND THE MIDDLE EAR

I want to try to illustrate these considerations by discussing the inflammations of the middle-ear cleft which I believe form today our most important medical problem from the national point of view I know that I am suspect in making such a statement, for they have been my daily task between the wars First there are cases of acute inflammation of the previously undamaged middle-ear cleft, most of which get well by the processes of nature But a small number demand immediate action by the emergency team and are just as urgent as the most fulminating form of appendicitis, and as with appendicitis the final decision depends on the correct appreciation of a single physical sign Rigidity of the neck is to otitic meningitis of acute disease what rigidity in the abdomen is to commencing peritonitis, and this neck-rigidity may be as difficult to assess as that in the right iliac fossa One thing is certain when you see a discharging ear and a suspicion of rigidity of the neck it is your duty to see that, to quote Wilfred Trotter, " the patient should at the earliest possible moment be put in conditions where any operation that may become necessary can be most safely and quickly performed "

The death of a child is a tragedy, but from the national standpoint it is not merely the fact of death that matters, but the influence which this has on the lives of others When a father or a mother dies and leaves children destitute, the results are more far-reaching than when one of the children is taken away, and this is what happens when an intracranial complication of chronic ear disease arises, for they arise in middle age Every one of these cases is a drama, sometimes it has a happy ending and then we keep in touch with the patient for several years, greeting him with pride, knowing he would not be there if it had not been for us Sometimes it is a tragedy and our part ends in the post-mortem room, examining the intracranial contents to see what we can do in the next case to ensure that it may take a different course The tension of a week's wasted work dies down and leaves us in that state of mental collapse which leads us to push the whole matter out of our minds But it is only the end of the third act of tragedy for the family, left either without its wage-earner or without the mother We all hope to start our children in life where we left off, we are beginning to wonder whether this is a wise wish, but there it is With the extinction of the wage-earner that hope is gone The mother has to take his place and the general standard of living goes down, in many instances, to one in which nutrition and even decency are impaired When the mother dies it is worse, the loss of that life takes effect unto the third and fourth generation These cases put the inflammation of the middle-ear cleft in the forefront of medical problems of national importance, because they are a group of tragedies which could have been prevented —and which should be prevented in the future

Other results affecting the national weal follow failure to cure an acute inflammation of the middle-ear cleft An infant begins to learn by the sense of feel, then the sense of sight is brought into play When he learns to walk he passes out of infancy, and education may be said to begin In the early stages of education hearing is the master sense, he needs it to learn to speak and to pick up scraps of knowledge from those around I do not think that the importance of this stage of a child's education is sufficiently realised If there has been some hardness of hearing he may be so backward as to lead to a suspicion of mental deficiency One of the most difficult examinations in clinical medicine is to test the hearing at this age and to decide whether there is any deafness; but I consider that hardness of hearing which we can hardly call deafness is of serious consequence to the developing mind up to the age when a child can read, and read freely Thus every acute inflammation of the middle-ear cleft if it is not cured before it changes to chronic disease or before there is permanent damage to the middle ear, may alter the whole of the patient's life

An elaborate organisation has been set up by the Board of Education over the whole country, under the Children's Act of 1906, to deal with chronic ear disease in children of school age Doctors, nurses, teachers, and many other people have given their attention to this work, and nothing has come of it in thirty years. That is what we have to face chronic ear disease is incurable It can be prevented by curing the preceding acute inflammation, but once the cutaneous or other secondary organisms have become established the disease is in most cases incurable Many will say I am wrong But though they may have helped many cases of chronic otitis media to get well, these are very few compared with the number of the population going about with chronic ear disease We must approach the problem from a new aspect Let us consider how chronic ear disease affects life after the school age has been reached We may divide it into the effect on education and the effect on the wage-earning capacity For the seriously deaf child there are special schools with expert teachers, or arrangements are made for the child to sit in front of the class near the teacher But these form but a small part of the problem It is the children with an unassessable diminution of hearing, or with deafness

---

* A lecture given on the eve of Trafalgar day 1941, at Guy's Hospital

Prisoners of War

W S /Captain J B Sherman, M B Melb, R A M C, and W S /Captain I R I MacDonald, M B Edin, R A M C, have been posted as prisoners of war

Paddington Medical Society

A meeting of this society will be held at 3 45 P M, on Nov. 11, at St Mary's Hospital, when there will be a discussion on how to solve the night call problem in London

Chadwick Lecture

Mr Frederick Hiorns, F R I B A, will give a Chadwick lecture on Tuesday, Nov 11, at 2 30 P M, at the London School of Hygiene, Keppel Street, W C 1 He will speak on hygiene technique in building, or the economic, psychological and health aspects of surface treatment

Royal Faculty of Physicians and Surgeons of Glasgow

At the annual meeting of the faculty the following were elected office bearers for the ensuing year —president, Mr Roy Young, visitor, Mr James MacDonald, treasurer, Mr William Richard, librarian, Dr W R Snodgrass, other councillors Mr J Scouler Buchanan, Mr Donald Duff, Dr John Gardner, Dr Stanley Graham, Dr John Henderson, Mr J A C Macewen, Dr Donald McIntyre, Dr Noah Morris, Mr William A Sewell, and Mr J Forbes Webster

Alliance of Hospital Administrators

The councils of the Incorporated Association of Hospital Officers (which has hitherto limited its membership to the administrative staffs of voluntary hospitals) and the Incorporated Association of Clerks and Stewards of Mental Hospitals have recommended the fusion of their societies The new body will open its membership to administrative officers of local authority and other hospitals, and a committee will be set up to consider the recruitment and training of administrative hospital staff

Notes, Comments and Abstracts

TO RADIUM SMALLHOLDERS

IN addition to the radium held by hospitals under arrangement with the Radium Commission and King Edward's Hospital Fund there is an appreciable amount in the possession of small hospitals, medical practitioners and commercial firms, and the Minister of Health has now issued a pamphlet instructing these users how to protect their supplies All radium exceeding 1 mg in amount should, when not in use, be kept in a bore-hole or steel container of an approved type described in the pamphlet The bore-hole advised is 50 ft deep, and otherwise similar to that lately described by Lederman and Mayneord (*Lancet*, 1941, 2, 461) The container consists of a round or square block of mild steel with a narrow opening leading to a cavity in the centre to hold the radium The opening is closed by a screw plug The walls of the container must be not less than 3 in thick In a hospital in a vulnerable area not more than 350 mg should be in use at any one time Radon should be used instead of radium where possible and the treatment of patients by radium should not continue during an air-raid unless they are in a shelter If a bomb falls where radium is known to be, the medical officer of health should be at once informed He will have the area roped off and notify the Ministry of Health, who will arrange for experts to examine the site

SALAZOPYRIN IN RHEUMATISM

GOOD results are reported by Svartz,[1] in Stockholm, from the use of a compound of sulphapyridine and salicylic acid in rheumatism She had previously found that though sulphonamides alone were sometimes valuable in septic arthritis they had no effect on the ordinary rheumatic case, but it seemed possible that they might render the responsible organism more sensitive to the action of salicylates Simultaneous medication with sulphonamides and salicylates was therefore tried, but without effect Finally, however, Askelof and Willstædt prepared salicylazosulphapyridine, a preparation which is now produced commercially by Pharmacia of Stockholm under the name Salazopyrin. Svartz reports five cases of rheumatic polyarthritis successfully treated with this drug One woman of 33 had had polyarthritis since 1933 and when seen could only walk a few steps difficulty ; salazopyrin, 0 5 g four times daily, begun on Oct 29, 1940, by Jan 31, 1941, movements were almost normal and the patient felt well Another woman of 44 with arthritis of 1½ years' standing, chiefly affecting the knees and metacarpals, was given several courses of salazopyrin amounting in all to 900 tablets of 0 5 g each This lady found herself standing on a chair energetically chasing a moth The other cases reported are similar, except that one developed a toxic rash after treatment for 10 days with 1 g six times daily Svartz also reports four cases of ulcerative colitis in which administration of the drug was followed by complete remission of symptoms Salazopyrin is only slightly soluble in water, but its alkaline salts dissolve fairly well Part of it is excreted unchanged in the urine, causing an orange discoloration if the urine is alkaline It does not give immediate relief of rheumatic pain and it may therefore be necessary to give salicylates with it The dose recommended for adults is 1 g four to six times daily, and treatment can be continued for weeks or months The blood picture should be watched, since mild anæmia was seen in some patients, no serious toxic effects were noted, though the drug had sometimes to be withheld for a time because of a rash.

BOOKS FROM THE ARGENTINE

IN their new volume on primary malignant tumours of the bronchi and lungs (Buenos Aires Hachette Pp 101), which is the only modern book written in Spanish on this subject, Prof Julio Palacio and Prof Egidio Mazzei describe three new clinical pictures associated with pulmonary growths the osteo-arthropathic, in which hypertrophic osteo-arthropathy is the characteristic sign, the pseudocardiac which produces symptoms resembling angina pectoris, paroxysmal tachycardia or cardiac insufficiency, and a type in which Klumpke-Dejerine paralysis gives a valuable pointer in the diagnosis of carcinoma of the apex of the lungs Several years ago the authors were awarded the Alvarenga prize of the Paris Academy of Medicine for their work on atelectasis of the lung, and in discussing atelectasis caused by bronchial carcinoma they draw attention to two new signs which they have observed deviation of the trachea (palpable in the suprasternal notch) during inspiration, in cases of atelectasis of the superior lobe, and the radiological finding of an unusual degree of translucency in the lung adjoining the atelectic lobe

In his book "Las Neurosis en la Guerra" (Buenos Aires Aniceto Lopez Pp 251) Prof Gregorio Bermann discusses the place of psychology, psychiatry and psychotherapy in the treatment of people affected by war conditions During the Spanish civil war Professor Bermann was chief of the section of neurology and psychiatry at the military hospital at Madrid and his book is based on his own clinical experience Prof Emilio Mira, who spent some months at the Maudsley before taking up a post in South America, has written a foreword to the book

WARNER'S CALENDAR OF MEDICAL HISTORY —Messrs William R Warner & Co did not expect to be able to print further editions of their diary during the war, but they have obtained the authorisation of the paper control to publish a limited number—less than half of last year's edition The calendar is available only to members of the medical profession, and any doctor who is a regular user or who would like a copy for 1942 should write at once to Messrs Warner, Power Road, London, W 14

THE fact that goods made of raw materials in short supply owing to war conditions are advertised in this paper should not be taken as an indication that they are necessarily available for export

OUTBREAK C

This outbreak took place in the modern section of an older hospital serving a large industrial population. Unfortunately we did not hear about it until it was over, so that there was no opportunity of studying it at first hand. The maternity unit comprises 4 wards of 6–12 beds each, and 5 single or double rooms, distributed on two floors. The ground floor has its own labour-room and in addition an isolation unit and nursery. The first floor takes the larger number of patients, has 2 labour-rooms, an operating-theatre and 2 nurseries, one of them for premature babies. The total number of beds is 43.

Between July 2 and Sept. 29, 1940, 29 babies became ill in hospital, most of them in July and August. Many of the cases were severe and the fatality (38%) was the highest of this series. The characters of the epidemic were similar to those already described. One main difference in the regimen of this hospital as compared with the others is the preponderance in the use of cow's milk.

Period of epidemic prevalence (July 2–Sept. 29, 1940)	
Babies born in hospital during this period	206
Babies affected in hospital	29
Deaths from neonatal diarrhœa in hospital	11

EPIDEMIOLOGY AND ÆTIOLOGY

Further experience must be gained before adequate discussion under this heading is possible. Each of the three epidemics started explosively, so that considerable numbers of infants were affected within a week or two; after this they progressed more slowly, outbreaks A and B continuing for weeks or months till the hospital was closed. Whatever the causal agent, and by whatever mechanism fresh cases are promoted, it can be said that, once the trouble starts, known methods of isolation as practised do not seem capable of stopping it, and that the individual cases are mild, moderate or severe without reference to such factors as sex, birth-weight, age at onset or stage of the epidemic.

Season.—The outbreaks all began in the warm summer months. It is reported that epidemics may occur at any season. All that can be said is that outbreak B continued without remission through summer into winter (December).

Incubation period.—Certain criteria from A suggest that this is short—from 1 to 8 days.

Age-incidence.—Most babies in outbreaks A and B became ill within the first week of life—the great majority within a fortnight. However, the youngest infants are not alone susceptible, as a follow-up (part of B) revealed that many babies developed diarrhœa after being discharged from hospital apparently well. Again, in C, where for various causes numbers of infants were kept in hospital longer than the usual 10–14-day period after birth, 46% were older than a fortnight when first affected.

Causal origin.—In view of the early age (4 days) at which signs may appear, and the short incubation period, the possibility must be envisaged that the disease is congenital or at least transmitted from mother to child at, or immediately after, birth. In fact, the mothers were healthy for the most part and delivered of apparently healthy children, and where there was maternal illness (eclampsia, pyelitis, breast abscess) it seemed to be no more prevalent among the mothers of affected than among those of the unaffected children. No evidence was discovered to implicate as causal factors morbid conditions such as colds, influenza, furuncles or digestive disturbances among the medical or other staff. Many babies both ill and well had a mild conjunctivitis (? prophylactic use of silver nitrate). A few had minor sepsis of the umbilicus or subcutaneous abscesses. Preceding infections of the upper and lower respiratory tracts, or of the central nervous system, were not found. Terminal bronchopneumonia was noted in some and discovered in others at autopsy, as was also pus in the middle ear.

Routine bacteriological throat and stool cultures were obtained from babies, mothers, medical and domestic staff in outbreaks A and B, and stool cultures from the babies in C, but none of the usual pathogens was found. Cultures from pus in the middle ear revealed organisms of the coliform and diphtheroid groups, as well as occasional staphylococci [illegible] streptococci.

Morbid anatomy.—Careful autopsies were performed on 9 subjects: 1 in outbreak A and 8 in B. None showed changes of note. As a rule the intestinal tract was normal anatomically and histologically. In one or two cases the intestinal mucosa was slightly hyperæmic. The liver, adrenals, spleen, kidneys and central nervous system were little, if any, different from the normal. The presence of terminal bronchopneumonia and otitis media in some instances has been remarked on.

ONSET AND COURSE OF DISEASE

The onset may be sudden or insidious. All three epidemics included examples of both. In B, many of the cases began slowly and appeared to be difficult to recognise in the early stages. In cases of insidious onset the baby begins to suck less vigorously, or becomes indifferent to food, appears slightly limp and ceases to put on weight. These signs are often misinterpreted. The breast milk is thought to be insufficient and a complement of cow's or other milk prescribed. Again, the disease may begin with a mild diarrhœa or merely a green stool; or there may be slight vomiting or a definite loss of weight.

The sudden onset is characterised by profuse diarrhœa, and usually vomiting, and sometimes a dramatic loss in weight. Where the onset is early (4th or 5th day) the physiological drop in weight is at its maximum, or a gain in weight may have set in. A failure to gain, or a further dramatic drop, may be the first sign that the infant is affected. In outbreak C a few infants in the premature class simply showed signs of collapse with anorexia and a greyish or cyanosed appearance, and died in a day or two without diarrhœa or vomiting. This type of onset has also been noted in some aged victims of true dysentery.

In the milder type of case, the stools become rather frequent, 2–5 daily, relaxed or slightly loose, green or yellow in colour. The appetite is as a rule indifferent but may be quite good, and an alteration in the colour of the stools for several days on end may be the only sign of abnormality. Constitutional symptoms are barely discernible. There is no dehydration, no rise in temperature, and beyond a faint pallor and a failure to gain in weight progress seems satisfactory. The stools may become normal and the whole process be over in a few days. But relaxation of the stools may persist for a week or two, and though there may be a continued absence of the more serious symptoms the appetite will remain poor, and the return to birth weight will be considerably delayed.

In those moderately ill, the stools are more frequent—up to 7 or more in the 24 hours. They are apt to be loose or watery, bright green, or yellow or orange. The infant may vomit once a day or more often. The weight falls by 8–16 oz. within 3–4 days of the onset. The baby becomes listless or drowsy and feeds slowly and reluctantly, has a pale or greyish appearance, and may or may not be manifestly dehydrated. He looks somewhat toxic, and the temperature is unstable—rising or falling a degree or so above normal. The illness lasts at least a week, and is generally prolonged into the second or third week, when recovery sets in with improvement of the appetite and a slow but steady accretion of weight. The stools return to normal rather slowly, and tend to remain a little relaxed or green while the infant is much better in all other respects.

The really serious cases are unmistakable. They become worse rapidly with diarrhœa and vomiting and sudden loss in weight. Vomiting is usually serious, frequent, sometimes projectile, and occurs after food and fluid. It may precede the onset of diarrhœa by a day or two and there is often a degree of abdominal distension. The stools number 3–10 in the 24 hours, are loose or watery, and are apt to vary in colour from time to time from green of different hues to yellow or brown and, characteristically, orange. Colic is not a feature. The loss of weight is considerable—1–2 lb. for the average baby. There is serious dehydration, drowsiness alternating with irritability, and sometimes a degree of neck rigidity; but the fontanelle is sunken, and an examination of the cerebrospinal fluid will reveal no change. The face becomes ashen grey, the eyes sunken, and at intervals the lips may be cyanotic. The temperature hovers around 100° F., but may reach 103° F. or 104° F., and the infant looks profoundly toxic. Death usually not serious enough to warrant special arrangements, that waste the nation's energy, because they are not gaining as much from their education as they should. They go out into the world less expert than they should be, whatever their work, because their mental processes are not developed as much as they might have been.

The effect on wage-earning capacity is more uncertain. I do not believe that mere discharge from an ear ever results in a person losing work, having to take work of a lower standard, or having to go off duty. Once the patient has learned how to make a proper toilet of the meatus none of these things will happen; the only reason for his drawing sickness benefit is his doctor's suggestion that he should. There is no reason why anyone should stop work or be admitted to hospital on account of ear discharge without any other symptom. With deafness the problem is more intricate. Once a person is in work he does not lose work because of it. But a deaf man finds great difficulty in getting posts and in holding them; and he is often driven to do poorly paid menial work below the level for which his mental faculties qualify him. But the process does not necessarily end there; he may be driven down into the ranks of the unemployed, from whom come the unemployable. This national problem will in the future become more important because the effect of deafness, or even of hardness of hearing, is much greater in the woman than in the man. There are many jobs a man can continue to do with little or no hearing but very few in which a woman can retain her post.

We must look, then, on every case of acute inflammation of the middle-ear cleft that becomes chronic as a failure, not for any given doctor but for the medical profession as a whole. It is not a matter for specialists, it is one of those bits of medicine common to the whole profession. We must all try to realise that if we have under us a patient with an acute inflammation of the middle-ear cleft we have a short six weeks in which to get it well from the date on which the drum-head ruptures; and by well I mean with a healed drum and normal hearing. We must use that combination of preventive and social clinical medicine of which I spoke earlier, and it will need the teamwork of the whole fleet. But no-one will see the results of his own work; what we do today will take effect in A.D. 2000.

EPIDEMIC NEONATAL DIARRHŒA IN MATERNITY HOSPITALS

I.—CLINICAL ASPECT

GEORGE ORMISTON, M.D. EDIN., M.R.C.P.L.
(*Working for the Medical Research Council, London*)

SERIOUS outbreaks of diarrhœa among babies in maternity hospitals have been described of recent years. Excellent accounts of their epidemiological and clinical features have appeared in America (Barenberg et al. 1937,* Frant and Abramson 1937, Rice et al. 1937, Best 1938), where attention has been drawn to their widespread distribution, high morbidity and mortality, and unexplained ætiology. Apart, however, from a paper by Craig (1936) little has appeared to indicate the prevalence of neonatal disease of an epidemic character in this country. The purpose of this communication is to summarise the results of studies into the nature of three of these outbreaks in different cities in England during the latter half of 1940.

These epidemics, which are sometimes referred to as epidemic diarrhœa of the newborn, are probably more common than is generally realised. Because of their tendency to high morbidity and mortality it is important that their features should be recognised as early as possible. We hope that the present account will lead to their more frequent recognition.

The cause or causes of diarrhœa in the neonatal period have not been satisfactorily established, and the opportunity has been taken to pursue certain bacteriological investigations which will be described in a later section of this paper. The outbreaks will be labelled respectively A, B and C. A and B affected hospitals in widely separated cities in the south of England, and C a hospital in a large city in the industrial north.

OUTBREAK A

This occurred in a voluntary lying-in hospital of between 50 and 60 beds. The building is comparatively old and has 5 public wards and 7 small private rooms. There are 10 beds and 10 cots to a ward. There is a single labour room situated between the babies' bathroom and a distributing kitchen. The babies are washed, changed and fed (if not on the breast) in the bathroom. This leads to much contact between them. The hospital is understaffed. There is no division of duties, so that the same nurse attends the mother and feeds, changes and washes the infant. Breast-feeding is the rule, but, when cow's milk is necessary, a pasteurised product is used, suitably diluted, and acidified with lactic acid. It is stored in a refrigerator in a special milk room. Glucose water is given to all babies.

The first baby became ill on May 10, 1940, with sudden loss of weight, severe diarrhœa and some vomiting, and exhibited other symptoms such as drowsiness, dehydration, elevated temperature, a toxic appearance and a hoarse cry. Thenceforth, cases of varying severity appeared every few days through June into July. All the wards and all the babies in the private rooms were affected, and though measures were taken to check it the outbreak persisted until the hospital was closed to further admissions.

Period of epidemic prevalence (May 2–July 20, 1940)

Babies born during this period	250
Babies who exhibited symptoms in hospital	27
(10 came under our observation.)	
Deaths from neonatal diarrhœa in hospital	5
(Deaths at home are not accounted for.)	

OUTBREAK B

This concerned the maternity department of a municipal hospital serving a large city about 130 miles from A. The department is of modern construction, and was opened in 1939. It consists of two identical one-storied buildings separated by a grass plot and with no indoor communication. Each comprises two wings joined together in a wide V facing roughly south. Each wing is subdivided into 11 single or double rooms and 2 small wards of 3 beds. The total number of beds in the department amounts to 88.

By contrast with A, the babies sleep together in a large central nursery, and here they are changed and fed if not on the breast. A bathroom and an isolation room adjoin the nursery. Cots are placed side by side on the framework of a movable trolley which is wheeled along the passage to the respective rooms at feeding time. The artificial foods in use include pasteurised milk, Nestle's, Trufood and Allenbury's. These are kept in the cupboard of a kitchen used for food distribution to the mothers, and there is no refrigerator. Glucose water is given to all babies. Here again the nurses share the duties of attending to mother and child. Each wing has its own labour-room and a separate personnel. A swing door in the passage between the wings can be closed to ensure the mechanical isolation of one wing from another.

When the outbreak came under our notice it appeared to be confined to one wing, where the first diagnosed case occurred on July 7, 1940, and the last on July 27. Out of 42 babies exposed, 11 became ill in hospital at intervals of a day or two; a follow-up inquiry revealed that an additional 12 babies developed the disease within a few days of reaching home and must have been discharged during the period of incubation.

Months later unmistakable cases were recognised in both wings of the twin block. The evidence suggests that the outbreak really began about the middle of June and ran without intermission in one wing or another until it was checked in December. Many deaths occurred, and though all the cases had pronounced gastro-intestinal symptoms, the stated cause of death was rarely connected with or attributed to them. The closing of a block about the third week of November appears to have stopped the outbreak.

Period of epidemic prevalence (June 17–Dec. 15, 1940)

Babies born during this period	540
Minimum number of babies affected in hospital	83
(25 came under our observation.)	
Deaths from neonatal diarrhœa in hospital	25

---

* References will be found at the end of the second paper.

spore-bearing bacteria or by other organisms were present in the fæces With these objects in view a fairly elaborate technique was designed of which the following is a summary

TECHNIQUE

A film of the fæces was stained by Gram's method and xamined to see if there was any obvious abnormality in the lative numbers of bacterial types present

Search for organisms of the salmonella and dysentery roups was made by direct plating on MacConkey's agar, and r organisms of the salmonella group in addition by preliminary enrichment in brilliant green and tetrathionate broths

A suspension of fæces was made in N/4 Ringer solution, tandardised by opacity to 3000 million coliform bacilli per ml , and treated as follows (*a*) One part was heated to 70° C or 10 minutes and plated out in duplicate on a glucose blood gar medium One plate was incubated aerobically and the ther anaerobically to detect spore bearing organisms *b*) The other part was not heated Instead, successive tenfold ilutions were made in N/4 Ringer, and 0 1 ml quantities of he 10^{-2}, 10^{-3}, 10^{-4}, and 10^{-5} dilutions were spread on plates of ry blood agar, glucose blood agar (Eggerth and Gagnon 1933), r liver glucose blood agar (Eggerth 1935), which were incubated anaerobically in a modified McIntosh and Fildes jar nd examined usually after 48–72 hours and then again after our or five days These plates were used for determining the relative numbers and types of micro-organisms present The identification of the different types was carried out by the sual routine methods Preliminary observations failed to eveal any advantage in the incubation of plates aerobically s well as anaerobically, and aerobic incubation was therefore iscontinued

The standard suspension was centrifuged at high speed, and tested for toxicity by the inoculation of 0 1–0 2 ml of the supernatant fluid intravenously into mice, and sometimes intraperitoneally as well

The fæces were usually examined on the same day as that on which they were passed If they arrived too late to be examined the same day, they were kept in the refrigerator overnight In some instances they were transmitted by post or rail and did not arrive till the following day Experimental observations on healthy infant stools subjected to these different methods of storage showed that little change in the normal flora resulted Fæces from sick babies were often inoculated immediately after collection on to MacConkey agar plates, in case dysentery bacilli should be present and die out during transmission to the laboratory

FINDINGS IN NORMAL NON-CONTACT INFANTS

At Oxford specimens of stools from 21 healthy noncontact infants aged 7–23 days were examined, and at Cambridge from 36 healthy non-contact infants aged 3–16 days These infants were all in maternity homes free from neonatal diarrhœa All infants were breast fed, though complementary feeds of modified cow's milk were given to a few of them The results are recorded in table I The figures on the whole agree very closely Oxford recorded a slightly higher proportion of coliform bacilli and Cambridge a slightly higher proportion of lactobacilli, but in view of the great variation in frequency to which all groups of organisms were subject in fæces from different infants no weight can be attributed to this discrepancy It will be seen that about 80% of the organisms cultured from the fæces belonged to the lactobacillus group, about 10% to the group of coliform bacilli, and about 4% each were streptococci and staphylococci Organisms of the Gram-negative bacteroides group (Eggerth and Gagnon 1933, Weiss and Rettger 1937, Misra 1938) and of the clostridium group were rarely present

Examination of the individual strains showed that practically all of the lactobacilli were of the *bifidus* type Most of the coliform bacilli were *Bact coli* I type (Report 1930), though occasional strains were identified as *Bact aerogenes*, or belonged to the late-lactose-fermenting or paracolon groups Proteus seemed to be very uncommon Of the streptococci present only a proportion were studied fully The great majority of these corresponded to *Streptococcus fæcalis*, being heat-resistant diplococci, fermenting mannitol but not raffinose, producing the characteristic acid clot with decolorisation in litmus milk, and falling into Lancefield's group D A few of the strains produced true β-hæmolysis, but most were α-hæmolytic With one exception the staphylococci were of the *albus* type and were coagulase-negative *Staphylococcus aureus* was never found in stools from healthy infants at Oxford, and only once at Cambridge The very few anaerobic spore-bearers that were isolated seemed to be closely related to, if not identical with, *Cl paraputrificum*, Bienstock (Hall and Snyder 1934)

These findings are in general accord with the classical observations of Tissier (1900), who first drew attention to the great predominance of *Lactobacillus bifidus* in the stools of healthy breast-fed infants

The intravenous inoculation of mice failed to reveal the presence of any soluble toxin in the stools At Oxford the animals remained alive and well till they were killed on the fifth day or later At necropsy nothing abnormal was found At Cambridge the animals were kept under observation for a longer time Most of them died in 10–35 days after injection No obvious changes were seen post mortem, but from the heart blood or peritoneal cavity coliform bacilli were cultivated These results were attributed to chronic infection with organisms present in the supernatant fluid of the fæces suspensions

FINDINGS IN OUTBREAK A

Samples of stools from 18 *normal contact* infants aged 1–22 days were examined at Cambridge with the results shown in table II Compared with the findings in normal non-contact infants at Cambridge (table I) considerable differences are noticeable The lactobacilli constitute only a small proportion of the fæcal flora, while the coliform bacteria and the staphylococci are preponderant Too much attention should not be paid to these differences, since owing to the large number of specimens received at once the full quantitative technique could not be carried out, and the figures are therefore open to criticism

Samples of stools from 9 sick babies suffering from diarrhœa were examined at Cambridge and 3 at Oxford Macroscopically the stools did not differ greatly from those of the healthy controls Mucus was not infrequently present in small quantity, but not more often than in the stools of the control babies Pus or blood was never observed With few exceptions the reaction was acid to litmus The bacteriological findings are summarised in table II Compared with the figures for normal contact infants in the same hospital, the lactobacilli are seen to be more numerous and the staphylococci less numerous The figures for the coliform bacilli and for the streptococci are much the same In 6 cases the stools were examined after recovery , the results were not appreciably different from those in the early stage of the disease

The number of samples examined in this outbreak was relatively small and the observations on the control normal contact infants were not altogether satisfactory There does not appear, however, to be any considerable difference in the bacterial flora of the stools from the sick and healthy infants in the same hospital, and certainly none that would suggest an adequate cause for the occurrence of diarrhœa

No organisms of the salmonella or dysentery groups were isolated from any of the stools, and in none of them was a soluble toxin demonstrated by mouse inoculation

FINDINGS IN OUTBREAK B

Samples of fæces from 14 normal contact infants were examined at Oxford and 10 at Cambridge The results are given in table III The Cambridge figures showed a lower proportion of lactobacilli and of coliform bacilli and a higher proportion of streptococci than the Oxford figures Taken together it will be seen that the chief difference in the distribution of organisms from that in healthy non-contact infants at Oxford and Cambridge (table I) is that the lactobacilli, though still dominant, are less numerous, and the coliform bacilli, and particularly the streptococci, are more numerous

From sick infants suffering from diarrhœa Oxford examined 10 stools and Cambridge 12 Macroscopically most of the stools were similar to those of healthy babies on a milk diet Mucus was not infrequently present in small quantity, as it was in the stools of the control contact infants, but pus and blood were absent With few exceptions the reaction was acid to litmus The bacteriological findings are summarised in table IV At Oxford a higher proportion of lactobacilli and a lower occurs within ten days, sometimes sooner, and generally within a fortnight Alternatively the symptoms may abate and slow recovery set in

So far as our limited observations go, complications do not appear to be common Otitis media is seldom obtrusive, but too few autopsies were undertaken to enable us to judge its real incidence The same may be said of bronchopneumonia, which when it occurred generally appeared in the final stages of the illness

PROGNOSIS AND TREATMENT

The prognosis is good in mild and moderate cases, and bad in those defined as serious Of those considered serious 62% in outbreak A and 81% in B died The onset of frankly fluid stools, repeated vomiting, restlessness and a hoarse cry worsen the prognosis The colour of the stools means little Orange stools may be present in mild cases as in serious The type of feeding may have some influence on the outcome In outbreak B, 14% of 51 sick infants entirely breast fed died, contrasted with 60% of 30 given artificial milks with or without breast milk In outbreak C, all the infants were being fed on cow's milk mixtures when they developed the disease, and the case-fatality was 38%

No treatment is specific In all but the mildest, parenteral administration of nutrient and salt-replacement fluids, and of blood or plasma is necessary In outbreak C, sulphapyridine was tried in some cases without success Sulphathiazole was tried in those instances where staphylococci were isolated from the stools The presence of these organisms is of problematical significance, so far as our investigations go, and the drug appeared of little value Breast milk would seem to be the feeding of choice

There is only one effective means of halting the spread of the epidemic, and that is to close the entire hospital to admissions, discharge the patients, and thoroughly clean and disinfect the wards before reopening in a week or ten days' time

COMMENT

Neonatal diarrhœa of an epidemic character has recently been described by Rice and his colleagues (1937) as a disease sui generis, using such criteria as (1) its apparent limitation to babies in the first month of life to the exclusion of older infants , (2) the apparent absence of parenteral disease to which it might be secondary , and (3) its non-identification with any known enteral disease However, during infancy the syndrome of diarrhœa, vomiting and associated effects identical with that of neonatal diarrhœa may arise from a number of infections well recognised or obscure, and until it has been established that epidemics of diarrhœa among the newborn are due to one and not to various ætiological agents the basis for regarding them as specific must rest on an insecure foundation

Meantime, the term " epidemic diarrhœa of the newborn " will serve a useful purpose if it leads to the more critical scrutiny of infants during their sojourn in hospital, and to the recognition of diarrhœa of an epidemic character at an early stage Mild cases are easily missed Slight loss of weight or vomiting in very young infants is a customary experience from irrelevant causes, and apt to be regarded casually by nurses and even experienced sisters The occasional green stool is a commonplace, and it is unnecessary to exaggerate the importance of these minor symptoms But it should be borne in mind that for a period of weeks they may be the only token that one baby after another is being affected by the disease in question, until there is a sudden flare-up of serious cases, some of which will be fatal Another danger is that a considerable proportion of babies may be discharged apparently well but incubating the disease They are lost sight of Many of them will be admitted to children's hospitals, where the origin of the disease is never suspected In fact the number affected by epidemic diarrhœa and the total mortality is probably much greater than one may conclude from a mere study of maternity hospital statistics

Epidemic diarrhœa of the newborn is not a new disease It has probably occurred as long as maternity hospitals have been in existence But the gravity of its effects have not been sufficiently realised The repetition of an outbreak in the same institution does not appear to be common until, perhaps, after the lapse of many years, so that hospital staffs are not familiar with it, and may not tackle it boldly at the beginning

Furthermore we have the impression that where an outbreak does arise the hospital authorities tend to be unduly reticent, fearing perhaps for the reputation of the place Until we are able to prevent these outbreaks it is probable that they will become more common with the expansion of hospital facilities and the decreasing number of confinements in the home If what has been described in these three epidemics reflects, as it may well do, a state of affairs occurring in other large centres of population, the total of wasted life and effort must be already considerable, and one that the nation cannot afford, least of all now

When an outbreak is suspected no effort should be spared to determine its true nature, and until this has been done rigid methods should be employed to safeguard those as yet unaffected When a definite diagnosis has been reached the hospital should be closed at once and the patients discharged If, at the same time, a careful investigation could be made and the results brought to the notice of the profession the accumulated data would add to our knowledge and might aid in the solution of the problem

SUMMARY

Three outbreaks of diarrhœa confined to newborn babies arose during the latter half of 1940 in maternity hospitals serving three widely separated cities in England They were essentially similar in their epidemiological and clinical features Large numbers of infants were affected and there was an aggregate case-fatality of 29%

It is suggested that outbreaks of neonatal diarrhœa are of more general occurrence than is realised, and may constitute an important factor in the maintenance of high neonatal mortalities

It is important that the nature of these outbreaks should be recognised at an early stage so that measures can be taken for the safety of present, and the prevention of future, contacts

(From the Emergency Public Health Laboratory, Department of Pathology, Cambridge, and the Emergency Public Health Laboratory, School of Pathology, Oxford)

HITHERTO the bacteriological findings in neonatal diarrhœa, or epidemic diarrhœa of the newborn as it is often called, have been variable and inconclusive In the United States McKinlay (1937) isolated an unidentified species of salmonella from the stools Kimberley (1939) found *Clostridium welchii* to be the predominating organism in the stools, but he did not regard it as of any ætiological significance Costello and Lind (1939) attributed the disease to a pathogenic strain of *Proteus vulgaris* associated with *Bacterium coli* Cron, Shutter and Lahmann (1940) cultured hæmolytic streptococci from the throat and from the stools of all the cases examined, and from the peritoneal fluid in 10 out of 13 cases coming to autopsy Frant and Abramson (1938), Greenberg and Wronker (1938), and Forbes and Olsen (1939), on the other hand, failed to find any bacteria of importance In this country Bloch (1941) states that in the outbreak he studied infection was obviously respiratory, and that staphylococci were found in the nose of some of the cases and contacts

In starting our inquiry it seemed important (*a*) to make as complete a study as possible of the bacterial flora of the fæces of normal and affected infants, and to find out whether the qualitative or quantitative distribution of organisms in the stools was disturbed during the course of the disease , (*b*) to search for known pathogenic organisms, such as those of the salmonella and dysentery groups , and (*c*) on the analogy of lamb dysentery to determine whether toxins formed by anaerobic

TABLE IV—OUTBREAK B DISTRIBUTION OF BACTERIA IN FÆCES OF SICK INFANTS

Type	Oxford (10 infants)			Cambridge (12 infants)			Oxford and Cambridge (22 infants)		
	Samples positive	Per cent of flora		Samples positive	Per cent of flora		Samples positive	Per cent of flora	
		Limits when present	A M		Limits when present	A M		Limits when present	A M
Lactobacilli	9	9–98	71	11	5–87	50	20	5–98	60
Coliform	9	1–91	22	11	10–100	38	20	1–100	31
Streptococci	4	< 1–10	2	5	2–28	5	9	< 1–28	4
Staphylococci	5	< 1–22	5	2	2–58	6	7	< 1–58	5
Clostridia	5	< 1	< 1				5	< 1	< 1
Other organisms*				3	4–6	1	3	4–6	1

* Other organisms were proteus and yeasts

(3) *Infection with a pathogenic organism that does not develop readily in culture*—Though the media we used are able to grow most organisms that are likely to be met with in the intestine, it is possible that some pathogenic organism may have been present in the fæces of the sick infants which failed to develop under the cultural conditions we were employing We do not regard this as probable, since if such an organism had been present in anything but small numbers, it would probably have been detected in the direct smear examination Nevertheless, in any future investigation the greatest variety of culture media and of cultural conditions should be employed in the hope of detecting some organism whose requirements are different from those of the more usual pathogenic intestinal bacteria

(4) *A toxin formed by an organism in the intestine*—The occurrence of dysentery in newborn lambs due to the formation in the intestine of a powerful toxin by *Cl welchii* type B affords a strong analogy for the possibly similar causation of neonatal diarrhœa in human infants This line of investigation seemed all the more promising since Kimberley (1939) had recently reported the finding of *Cl welchii* as the predominant organism in the stools of infants suffering from neonatal diarrhœa Our attempts to confirm this hypothesis, however, met with complete failure Anaerobic organisms were seldom found, and then only in small numbers. Moreover, the direct examination of the fæces for soluble toxins to mice proved negative The possibility that a toxin was formed by *Staph aureus* in the intestine seemed very unlikely, since these organisms were rarely found The formation in the intestine of toxic split-products from one of the milk proteins by a bacterial species, or combination of species, not generally considered pathogenic must also be envisaged, but so far we have no evidence to support it

(5) *A bacterial toxin ingested with the food*—*Staph aureus* is a not uncommon cause of acute mastitis in cows The milk may contain an enterotoxin formed as the result of the growth of the staphylococci in the udder, though more usually the toxin is not present in sufficient quantities to be detectable till the milk has been left for a few hours at a suitable temperature after withdrawal (Barber 1914, Crabtree and Litterer 1934, Shaughnessy and Grubb 1936) It seemed not impossible that an enterotoxin-producing strain of *Staph aureus* might gain access to a maternity ward, infect the breasts of some of the mothers, and lead to the development of toxicity in the milk This hypothesis received some support from the finding in outbreak C that a number of strains of *Staph aureus* isolated from the milk of a tuberculin tested herd supplying the hospital were able to produce an enterotoxin It received further support when we found that a number of the mothers of sick babies in outbreak B were secreting milk containing pathogenic *Staph aureus* When we examined these strains, however, by the kitten test, none of them was found capable of forming an enterotoxin Moreover subsequent observations showed that coagulase-positive strains of *Staph aureus* are frequently present in the milk of healthy mothers with healthy babies While we would not like to exclude the hypothesis of toxin formation by staphylococci or some other organism in the maternal breast, we must admit that the evidence so far available is far too meagre to justify our regarding it as more than a possible cause in some outbreaks

(6) *Secondary to a systemic infection with an unknown organism*—It is possible that the diarrhœa may result from general toxæmia due to infection of some part of the body other than the intestine, such as the middle ear or lung No opportunity was afforded at Oxford or Cambridge of exploring this suggestion, but the results of examinations made locally as well as the findings of other workers do not seem to lend it much support

(7) *A virus infection*—To the best of our knowledge no primary infection of the human intestine with a virus has so far been described, though in certain virus infections of animals, such as rinderpest of cattle and ectromelia of mice, extensive invasion of the intestine may occur The high degree of infectivity of neonatal diarrhœa is consistent with a virus causation, and this possibility should be kept in mind in any future investigation In only one outbreak was post-mortem material examined for the presence of viruses—by Dr van den Ende and Miss Dora Lush—and the results were entirely negative. Prof James McIntosh has suggested in conversation that the condition may be due to infection of the parasympathetic ganglia with a neurotropic virus leading to increased peristalsis This suggestion again should be borne in mind in any future investigation, but the very short incubation period of the disease in some cases is slightly against it

(8) *Infection with a protozoon*—*Giardia intestinalis* and certain other protozoa are responsible for enteritis in children, and it is conceivable that neonatal diarrhœa may be primarily a protozoal infection Although this possibility cannot be entirely excluded, it may be noted that examination at Cambridge of unstained films of fæces from outbreaks A and B failed to reveal the presence of any protozoa

Other hypotheses might be suggested, but to no particular purpose The comparatively mild disturbance in the normal bacterial flora of the intestine in infants suffering from neonatal diarrhœa—a disturbance that may easily be due to the more rapid passage of food through the intestine with consequently insufficient time for the lactobacilli to proliferate in the lower bowel—suggests that the disease is not due to the prodigious multiplication of an abnormal bacterium gaining access to the intestine The relatively insignificant post-mortem findings, both macroscopic and microscopic, are suggestive more of a toxæmic condition or a virus infection than of a primary bacterial enteritis

From a bacteriological point of view it is entirely possible that neonatal diarrhœa is not due to a single pathogenic agent The diverse findings that have been recorded in this disease (see opening paragraph of this article) are curiously reminiscent of those in summer diarrhœa of children, in which the predominant organism in different countries of the world has been found to be *Bact shigæ*, *Bact flexneri*, *Bact sonnei*, a member of the salmonella group, *P vulgaris*, *P morgani*, *Pseudomonas pyocyanea*, or *Cl welchii* (see Topley and Wilson 1936) The gastro-enteritis of infants that have passed the neonatal period, which has recently been described by Dobbs (1941) as the greatest menace to infants with pyloric stenosis admitted to English hospitals, likewise remains of uncertain ætiology It may be that all these different diarrhœal complexes are of similar causation, and are due to (*a*) a primary virus infection or (*b*) some systemic bacterial infection or metabolic disturbance, either or both of which paves the way for the proliferation in the intestine of any pathogenic or potentially pathogenic organism that happens to be present In this connexion it may be that organisms which are non-pathogenic to adults may under favourable conditions assume pathogenicity for infants and young children

CONCLUSIONS

1 Though it would be unjustifiable to draw any definite conclusions from the limited material we have examined, there seems no evidence to suggest that organisms of the salmonella or dysentery groups are concerned in neonatal diarrhœa

Fæces at Oxford were plated on liver blood glucose agar at Cambridge on blood agar or glucose blood agar

A M = arithmetic mean

proportion of coliform bacilli were found than at Cambridge, otherwise the results agree fairly closely Compared with the findings from the control contact infants in institution B (table III), the combined figures for the sick infants show a higher proportion of coliform bacilli and a lower proportion of streptococci

From no sample of fæces were salmonella or dysentery bacilli isolated, and no sample was found to be toxic for mice

Since it seemed possible that neonatal diarrhœa might be due to a staphylococcal enterotoxin elaborated in the maternal breast, an examination was made for staphylococci in the milk of sick babies' mothers Ten strains of these organisms were isolated from seven samples of milk Four of them proved to be of the *aureus* and six of the *albus* type The four *aureus* strains were coagulase-positive and three of them produced an α-hæmolysin None of them produced a β-hæmolysin, and none of them produced enterotoxin as judged by the kitten test of Dolman, Wilson and Cockcroft (1936) The six *albus* strains were all coagulase-negative, hæmolysin-negative and enterotoxin-negative

Five strains of staphylococci were isolated at Oxford from the fæces of infants with neonatal diarrhœa Two of these were of the *aureus* type, and were coagulase-positive but enterotoxin-negative Three were of the *albus* type and were both coagulase- and enterotoxin-negative

FINDINGS IN OUTBREAK C

No samples of fæces were available from this outbreak, but six strains of staphylococci that had been isolated from the milk of a tuberculin-tested herd supplying the hospital were sent for examination Four of the strains were of the *aureus* type They were coagulase-positive, and produced an α-hæmolysin and an enterotoxin The enterotoxin formed by two of the strains was so powerful that the kittens died within 24 hours Only one strain was tested for *β-hæmolysin, and this was positive* Of the two other strains, one was of the *albus* type and the other produced an orange pigment Both were coagulase- *and enterotoxin-negative*

DISCUSSION

The main question at issue is What is the cause of neonatal diarrhœa ? The following possibilities must be considered

(1) *Specific infection with an organism of the salmonella or dysentery groups*—Though Hormaeche and his associates (Bonaba et al 1940) found that 20% of enteritis in infancy and childhood in Uruguay were due to salmonella infection, and 32% to dysentery infection we have completely failed to isolate any member of these groups of organisms It may be remarked that so far as we are aware Hormaeche did not examine any outbreak of neonatal diarrhœa With the exception of a single outbreak described by McKinlay (1937) who reported the isolation of an unidentified strain of salmonella from the stools of the infants during life and from the heart blood and viscera of one case at autopsy, no evidence has yet been adduced to incriminate these organisms in the causation of this condition

(2) *Infection with a normally non-pathogenic bacterium*—This is the view taken by Costello and Land (1939), who attribute the disease to a pathogenic strain of *P vulgaris* associated with *Bact coli* Cass (1941) likewise seems to take the same view She found an organism, which was identified, probably incorrectly, as *B lactis aerogenes,* in the fæces of 5 sick infants From 2 of the infants that died it was isolated from a consolidated lung and from an umbilical thrombus respectively Since, however, the same organism was found in the fæces of at least 4 out of 6 healthy infants (no mention is made of the findings in one of the infants), it seems very doubtful whether her conclusion is justified Our own findings show that the proportion of lactobacilli in the stools is diminished and the proportion of coliform bacilli, and to a less extent of streptococci,' increased Most of the coliform bacilli appear to be of the *Bact coli* I type and most of the streptococci appear to be of the enterococcus type belonging to Lancefield's group D Neither of these organisms can be regarded as abnormal inhabitants of the bowel, and their pathogenic rôle might therefore be discounted The fact, however, that these organisms were found in much the same proportions in the fæces of healthy contact infants in the same outbreaks, while they were present in much smaller proportions in the fæces of healthy non-contact infants in normal maternity homes makes one cautious in adopting such a conclusion Without further evidence it is clearly impossible to decide whether these organisms were the primary cause of the disease or whether their undue proliferation was secondary to a disturbance of the bowel caused by some other agent *Proteus vulgaris* was rarely met with, and its causative rôle in the two outbreaks that were investigated can be ruled out

(3) *Infection with a pathogenic organism that does not develop readily in culture* —Though the media we used are able to grow most organisms that are likely to be met with in the intestine, it is possible that some pathogenic organism may have been present in the fæces of the sick infants which failed to develop under the cultural conditions we were employing We do not regard this as probable, since if such an organism had been present in anything but small numbers, it would probably have been detected in the direct smear examination Nevertheless, in any future investigation the greatest variety of culture media and of cultural conditions should be employed in the hope of detecting some organism whose requirements are different from those of the more usual pathogenic intestinal bacteria

(4) *A toxin formed by an organism in the intestine* —The occurrence of dysentery in newborn lambs due to the formation in the intestine of a powerful toxin by *Cl welchii* type B affords a strong analogy for the possibly similar causation of neonatal diarrhœa in human infants This line of investigation seemed all the more promising since Kimberley (1939) had recently reported the finding of *Cl welchii* as the predominant organism in the stools of infants suffering from neonatal diarrhœa Our attempts to confirm this hypothesis, however, met with complete failure Anaerobic organisms were seldom found, and then only in small numbers Moreover, the direct examination of the fæces for soluble toxins to mice proved negative The possibility that a toxin was formed by *Staph aureus* in the intestine seemed very unlikely, since these organisms were rarely found The formation in the intestine of toxic split-products from one of the milk proteins by a bacterial species, or combination of species, not generally considered pathogenic must also be envisaged, but so far we have no evidence to support it

(5) *A bacterial toxin ingested with the food* —*Staph aureus* is a not uncommon cause of acute mastitis in cows The milk may contain an enterotoxin formed as the result of the growth of the staphylococci in the udder, though more usually the toxin is not present in sufficient quantities to be detectable till the milk has been left for a few hours at a suitable temperature after withdrawal (Barber 1914, Crabtree and Litterer 1934, Shaughnessy and Grubb 1936) It seemed not impossible that an enterotoxin producing strain of *Staph aureus* might gain access to a maternity ward, infect the breasts of some of the mothers, and lead to the development of toxicity in the milk This hypothesis received some support from the finding in outbreak C that a number of strains of *Staph aureus* isolated from the milk of a tuberculin-tested herd supplying the hospital were able to produce an enterotoxin It received further support when we found that a number of the mothers of sick babies in outbreak B were secreting milk containing pathogenic *Staph aureus* When we examined these strains, however, by the kitten test, none of them was found capable of forming an enterotoxin Moreover, subsequent observations showed that coagulase-positive strains of *Staph aureus* are frequently present in the milk of healthy mothers with healthy babies While we would not like to exclude the hypothesis of toxin formation by staphylococci or some other organism in the maternal breast, we must admit that the evidence so far available is far too meagre to justify our regarding it as more than a possible cause in some outbreaks

(6) *Secondary to a systemic infection with an unknown organism* —It is possible that the diarrhœa may result from general toxæmia due to infection of some part of the body other than the intestine, such as the middle ear or lung No opportunity was afforded at Oxford or Cambridge of exploring this suggestion, but the results of examinations made locally as well as the findings of other workers do not seem to lend it much support

(7) *A virus infection* —To the best of our knowledge no primary infection of the human intestine with a virus has so far been described, though in certain virus infections of animals, such as rinderpest of cattle and ectromelia of mice, extensive invasion of the intestine may occur The high degree of infectivity of neonatal diarrhœa is consistent with a virus causation, and this possibility should be kept in mind in any future investigation In only one outbreak was post-mortem material examined for the presence of viruses—by Dr van den Ende and Miss Dora Lush—and the results were entirely negative. Prof James McIntosh has suggested in conversation that the condition may be due to infection of the parasympathetic ganglia with a neurotropic virus leading to increased peristalsis This suggestion again should be borne in mind in any future investigation, but the very short incubation period of the disease in some cases is slightly against it

(8) *Infection with a protozoon* —*Giardia intestinalis* and certain other protozoa are responsible for enteritis in children, and it is conceivable that neonatal diarrhœa may be primarily a protozoal infection Although this possibility cannot be entirely excluded, it may be noted that examination at Cambridge of unstained films of fæces from outbreaks A and B failed to reveal the presence of any protozoa

Other hypotheses might be suggested, but to no particular purpose The comparatively mild disturbance in the normal bacterial flora of the intestine in infants suffering from neonatal diarrhœa—a disturbance that may easily be due to the more rapid passage of food through the intestine with consequently insufficient time for the lactobacilli to proliferate in the lower bowel—suggests that the disease is not due to the prodigious multiplication of an abnormal bacterium gaining access to the intestine The relatively insignificant post-mortem findings, both macroscopic and microscopic, are suggestive more of a toxæmic condition or a virus infection than of a primary bacterial enteritis

From a bacteriological point of view it is entirely possible that neonatal diarrhœa is not due to a single pathogenic agent The diverse findings that have been recorded in this disease (see opening paragraph of this article) are curiously reminiscent of those in summer diarrhœa of children, in which the predominant organism in different countries of the world has been found to be *Bact shigæ Bact flexneri*, *Bact sonnei*, a member of the salmonella group *P vulgaris P morgani*, *Pseudomonas pyocyanea*, or *Cl welchii* (see Topley and Wilson 1936) The gastro-enteritis of infants that have passed the neonatal period, which has recently been described by Dobbs (1941) as the greatest menace to infants with pyloric stenosis admitted to English hospitals, likewise remains of uncertain ætiology It may be that all these different diarrhœal complexes are of similar causation, and are due to (*a*) a primary virus infection or (*b*) some systemic bacterial infection or metabolic disturbance, either or both of which paves the way for the proliferation in the intestine of any pathogenic or potentially pathogenic organism that happens to be present In this connexion it may be that organisms which are non-pathogenic to adults may under favourable conditions assume pathogenicity for infants and young children

CONCLUSIONS

1 Though it would be unjustifiable to draw any definite conclusions from the limited material we have examined, there seems no evidence to suggest that organisms of the salmonella or dysentery groups are concerned in neonatal diarrhœa

2 There is no evidence of the formation of soluble toxic substances by anaerobic bacilli in the intestine, analogous to what occurs in lamb dysentery

3 There is no evidence of the formation of toxic substances under bacterial action in the maternal breast, though this possibility cannot be excluded

4. The fact that the fæcal flora in diseased infants differs only slightly from that in normal infants under similar environmental conditions suggests that neonatal diarrhœa is not ordinarily caused by an abnormal organism gaining access to the intestine and multiplying prodigiously

5 It seems more probable that neonatal diarrhœa results from either (*a*) a virus invading the intestine, or possibly the parasympathetic ganglia, and giving rise to increased peristalsis , or (*b*) a systemic infection, intoxication, or general metabolic disturbance leading to the proliferation of any pathogenic or potentially pathogenic organism that happens to be present in the bowel

SUMMARY

Normal infants —A quantitative cultural examination was made at Oxford and Cambridge of the fæcal flora of 57 normal non-contact breast-fed infants, 3–23 days of age, in maternity homes free from neonatal diarrhœa On the average *Lactobacillus bifidus* was found to constitute about 80% of the organisms, coliform bacilli about 10%, and streptococci and staphylococci each about 4% Members of the clostridium group and of the bacteroides group were found infrequently, and then in only small numbers The proportions, however, in which the different organisms were present was subject to great variation from infant to infant Most of the coliform bacilli belonged to the *Bact coli* I type, and most of the streptococci to the enterococcus type *Staph albus* was found in rather more than half the infants, but *Staph aureus* was isolated only once

Infants with neonatal diarrhœa —The fæcal flora was studied in two outbreaks, a total of 34 infants being examined The proportion of lactobacilli was reduced to 30 and 60%, and the proportion of coliform bacilli increased to 55 and 31% respectively Very similar changes, however, were found in control healthy contact infants during the same outbreaks The proportion of streptococci and staphylococci showed but little change Organisms of the clostridium and bacteroides groups were seldom present No organisms of the salmonella or dysentery groups were found, and no evidence was obtained of the existence in the stools of soluble toxins for mice In one outbreak *Staph aureus* was isolated from the milk of a number of mothers with sick children and was found to be coagulase-positive and hæmolysin-positive None of the four strains studied, however, was able to form an enterotoxin On the other hand, four strains isolated in connexion with another outbreak from the milk of a tuberculin-tested herd supplied to the hospital were found to be coagulase-positive, hæmolysin-positive, and enterotoxin-positive.

NEPHRECTOMY IN UNILATERAL RENAL DISEASE WITH HYPERTENSION

G O RICHARDSON,
M B CAMB
ASSISTANT PATHOLOGIST,
ROYAL VICTORIA INFIRMARY,
NEWCASTLE ON-TYNE

G A SMART,
M D , B SC DURH , M R C P
MEDICAL REGISTRAR AT
THE INFIRMARY

THE association between renal disease and hypertension is well recognised In view of this it seems that cases of hypertension without clinically obvious renal deficiency are too often grouped as essential hypertension Schroeder and Steele[26] investigated 71 cases diagnosed as essential hypertension and found that 50 showed abnormalities of the urinary tract, 38 being unilateral Of 600 cases of hypertension, Maher and Wosika[17] demonstrated urological disorders in 101

In cases which have unilateral renal lesions amenable to surgical treatment, it is clearly of value to study the effects of therapy on the hypertension with a view to discovering possible ætiological agents We have recently had the opportunity of studying 2 such cases

CASE-HISTORIES

CASE 1 —A man, aged 35, was admitted complaining of frequent attacks of left sided renal colic About 4½ years before he had severe headaches and morning epistaxis, and a few months later was admitted to hospital for difficulty in walking and partial aphasia There he was found to have a right hemiplegia and a blood pressure of 200/130 mm Hg, his urine contained albumin but no red cells or casts , his blood urea was 26 mg per 100 c cm The symptoms disappeared with rest and he was discharged as a case of essential hypertension Two years later he was again complaining of headaches and epistaxis, but also of pain in the left loin which gradually increased in frequency and severity until he was readmitted to hospital on Aug 19, 1940 Examination showed slight involuntary movements of the right hand with increased deep reflexes in the arm and leg on that side and absence of the right abdominal reflexes , there was a right extensor plantar response The pulse was regular , the blood pressure varied from 235/140 to 245/140 There was slight enlargement of the heart to the left and an accentuated aortic second sound Urine albumin present , numerous pus cells, a few red cells and cellular casts Blood urea 30 mg per 100 c cm A radiogram showed opacities in the left renal area and intravenous pyelography localised these to the renal pelvis There was deficient excretion on the left side, but normal excretion on the right side

Nephrectomy was performed by Mr N Hodgson on Sept 2 At the lower pole the kidney substance was largely replaced by caseous material , in the mid zone there was a tuberculous focus completely destroying an area about 3 cm in diameter The pelvis was not dilated At the upper pole there was one area suggestive of hypertensive renal atrophy Histological examination showed active renal phthisis Outside the tuberculous areas there was an occasional sclerosed glomerulus, otherwise the glomeruli showed dilatation of the capsular spaces Some of the arterioles and a branch of the renal artery at the hilus showed muscular hypertrophy

The patient made a rapid recovery from the operation and there was immediate symptomatic improvement He was discharged from hospital on the 14th postoperative day, and has been seen at intervals in the succeeding 7 months While in hospital, and at his subsequent visits, the blood-pressure was taken under standard conditions After a transitory fall to below normal levels, as a result of postoperative shock, the pressure was maintained at a normal level for a time, and then rose slightly to the region of 150/100, where it has remained When last seen, hypertensive symptoms had completely disappeared, and the patient has joined the N A A F I and is prepared for foreign service

CASE 2 —A man, aged 55, was admitted to hospital complaining of a dull aching pain in the right loin of one week's

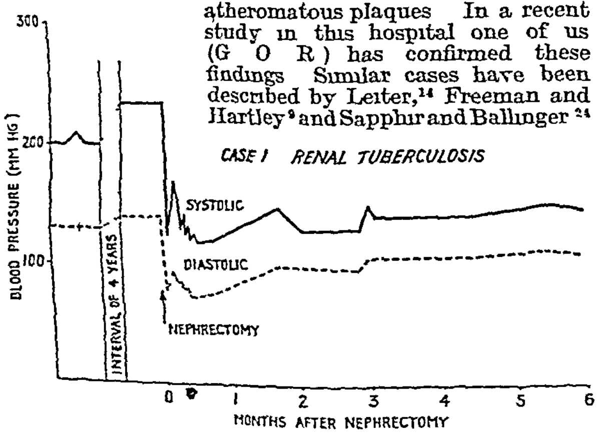
duration He had also noticed blood in his urine with occasional small clots A mass was felt in the region of the lower pole of the right kidney The blood pressure varied from 195/105 to 185/95 Cystoscopy and retrograde pyelography were performed on March 3, 1941 The right ureteric orifice was inflamed and pouting, the radiogram showed a filling defect of the right renal pelvis and major calyces Nephrectomy was performed by Mr W A Hewitson on March 10, 1941 More than half the kidney substance was replaced by yellow tumour nodules with numerous areas of hæmorrhage, the main renal vein at the hilus was almost occluded by tumour The histological appearances were typical of hypernephroma

The patient made an uninterrupted recovery The blood-pressure declined to 130/80, and has remained at this level

DISCUSSION

The relation between hypertension and a coincidental unilateral renal lesion is best demonstrated by the result of removal of the affected kidney We have been able to find 28 previously reported cases [1, 2, 5, 6, 7, 8, 13, 16, 19, 20, 21, 23, 25] An analysis of these cases shows that they fall into four groups, each of which has its experimental counterpart

1 *Renal arterial occlusion*—Goldblatt and his collaborators[10] have shown that partial occlusion of the main renal artery produced hypertension Leadbetter and Burkland[13] have recorded a case in a child with hypertension in which nephrectomy was performed for a ptosed kidney, the renal artery of which was found to be partially obstructed by a smooth-muscle tumour The operation resulted in a cure of the hypertension In an examination of autopsy material, Blackman[4] has shown that in most cases with essential hypertension there is partial occlusion of one or both main renal arteries by atheromatous plaques In a recent study in this hospital one of us (G O R) has confirmed these findings Similar cases have been described by Leiter,[14] Freeman and Hartley[9] and Sapphir and Ballinger[24]

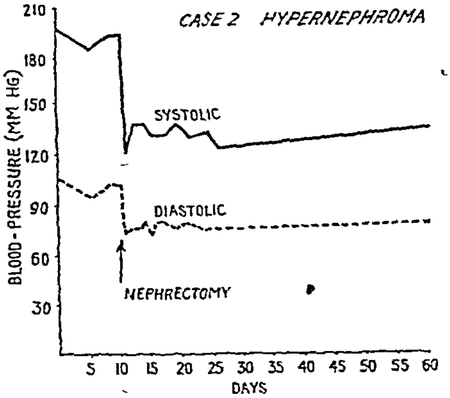


2 *Lesions resulting in partial occlusion of the renal vein*—Bell and Pederson[3] and Menendez[18] showed that experimental partial occlusion of the renal vein resulted in hypertension This has been recorded by Perry and Taylor[22] in an autopsy on a child with hypertension apparently due to thrombosis of the renal veins Our second case is highly suggestive of an ætiological association between partial venous occlusion and hypertension

3 *Diseases of the kidney substance*—The association of chronic diffuse nephritis with hypertension is too well known to require further comment Attention has lately been drawn to the occurrence of hypertension in cases of chronic pyelonephritis, even when the lesion is unilateral[15] Several cases of this type with successful surgical intervention have been reported, and our first case is another example Experimentally, chronic interstitial fibrosis of the kidneys produced by X rays has resulted in hypertension[12]

4 *Lesions causing obstruction to the outflow of urine*—Harrison and his colleagues[11] produced hypertension by occlusion of one or both ureters Clinical examples of this type are frequent

It appears that in most of the cases reported in the literature removal of the diseased kidney has been followed by a substantial and prolonged fall in the blood-pressure It might be claimed that such a fall would follow any major surgical operation Volini and Flaxman[illegible] have investigated the effect of a variety of non-specific operations carried out on hypertensive patients They have shown that, although in many cases there is definite symptomatic improvement, there is no alteration in the blood-pressure apart from the transitory fall due to postoperative shock In all except 5 of the recorded cases the blood-pressure fell to 150/100 or lower after unilateral nephrectomy, and remained at this level Of the exceptions, in one the pressure remained between 140/74 and 160/90 for a considerable time (unstated), but 11 years later it had risen to 190/122[8], no investigation of the remaining kidney was carried out at that time, so it is possible that it had become diseased At the time of operation 2 other reported cases[25] showed evidence of diminished renal function in the intact kidney so it seems probable that they were not cases of unilateral renal disease In the fourth unsuccessful case, the pathology was not clearly demonstrated[23] In the case recorded by Mulholland,[19] the lesion (renal calculus) had been present 14 years before, at which time the patient had refused operation When treatment was undertaken, severe cerebral symptoms were present; these decreased sufficiently after nephrectomy for the patient to do her normal work



It is premature to speculate about the mechanism whereby hypertension is produced in these cases but it is clear that a careful investigation of all cases of supposed essential hypertension will reveal many cases with lesions of one kidney amenable to surgical treatment The recorded cases show that when hypertension is associated with unilateral renal disease relief both of the hypertension and the symptoms will probably follow nephrectomy

SUMMARY

Two cases of hypertension, one of which had previously been classed as essential hypertension, are reported in which unilateral renal lesions were treated by nephrectomy with significant lowering of the blood-pressure

Similar cases reported elsewhere fall into four groups showing renal arterial occlusion, partial occlusion of a renal vein, diseases of the kidney substance, or lesions causing obstruction to the outflow of urine Each of these has an experimental counterpart

In view of the therapeutic results and the known association between unilateral renal disease and hypertension, all cases of chronic hypertension should have a complete urological investigation

We wish to thank Mr N Hodgson, Mr W A Hewitson and Dr J C Spence for permission to use the records of the cases which were under their care

BLACK-CURRANT PUREE AS A SOURCE OF VITAMIN C

WILFRID W PAYNE,
M B LOND , M R C P
PATHOLOGIST, E M S , BIOCHEMIST TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET

ELIZABETH TOPLEY,
M B LOND
MEDICAL OFFICER, E M S

THIS investigation was started to determine the minimal dose of vitamin C, in the form of a black-currant puree, that was required to supplement adequately the routine diet in some children's wards of an E M S hospital Black-currant puree was chosen as being the most satisfactory substitute for orange juice available (Olliver 1940) During the winter and spring the diet at the hospital was as good as the local food position allowed and probably better than that of many children in this country at the time Nevertheless it was found that the vitamin-C intake was unlikely to exceed 5 mg ascorbic acid a day and that only if the children ate up all their ration of greens One child, who had been in hospital for several months, actually developed mild clinical scurvy

In planning the investigation it was decided to adopt the simple technique of Pemberton (1940), owing to the difficulties entailed in collecting accurately over a given period urine from infants and small children in a ward In the morning the child passes a specimen of urine and is then given a test dose of 50 mg of ascorbic acid per stone weight After about 2½–3 hours urine is again passed and the specimen discarded The urine is passed again about 2 hours later The ascorbic acid in the first and third specimens is then estimated by the technique of Harris and Ray (1935) An increase of at least 3 mg per 100 c cm is taken to indicate a reasonable degree of saturation

RESULTS

Fifty-nine children were given a preliminary test and not one gave a positive result The children were then given a daily supplement either of synthetic ascorbic acid or of black-currant puree The puree used contained 0 8–0 9 mg ascorbic acid per g and was well tolerated even by the youngest children The usual dose was 50 mg of ascorbic acid or 1½ oz of puree (40 mg of ascorbic acid) Periodic re-tests at about weekly intervals were made to see if any improvement had occurred In only two out of thirty-five children in the hospital were there any signs of improvement after 9–20 days on the supplement, although healthy children living on a farm selected as a control group on a better diet became saturated in just over a week

It was then decided to saturate the children with a daily dose of 50 mg per stone and to re-test at three-day intervals (transport difficulties prevented more frequent testing) Fourteen children became saturated in the first 3-day period, and seven of these had previously been given 40–50 mg of ascorbic acid daily Six children took 3–6 days to saturate, and two of these had previously been given ascorbic acid Six children took over 6 days and one failed to become saturated in 24 days It is of interest to compare these results with those of Harris (1940) Using a somewhat similar saturation technique he found that subjects having a satisfactory diet gave a positive saturation test on the first or second day of the saturation dose, and that the worse the diet had been the longer was the time taken to obtain a positive result It will be seen that in many cases the degree of unsaturation was extreme

Once saturated, the children were given either ¾ or 1½ oz of black-currant puree daily (20 or 40 mg ascorbic acid) and were re-tested at intervals of 9–10 days If saturation was maintained on 1½ oz then ¾ oz was tried Unfortunately many of the children were discharged before the lower dose could be tried, so the attempts to find the minimal maintenance dose of ascorbic acid were only partially successful The average maintenance dose at different ages was as follows The results obtained have been expressed as mg of ascorbic acid per stone recorded at different ages

Ages	mg ascorbic acid per stone	Av
0– 3	11, 13, 17, 8, 16	15
3– 6	10, 4, 14	9
6– 9	6, 4, 7, 6, 7	6
9–12	4, 8, 10	7

It is probable that the actual minimal maintenance dose is less than these figures suggest It is hoped that further work will produce a more accurate result

A child of 1½ years with clinical scurvy was investigated in the earlier stage of this work She was cured by six daily doses of 4 oz black-currant puree and 1 oz a day was more than sufficient to maintain saturation

The diseases for which the children were admitted were various, both surgical and medical, and included such cases as talipes, harelip, mastoid (postoperative), cervical adenitis, asthma, debility, bronchiectasis and subacute nephritis, but by the time the maintenance test periods had been reached all but a few of the children were convalescent, afebrile and free from symptoms Eight cases either failed to saturate within 9 days or failed to maintain saturation on 40 mg per day, their diagnoses were chorea (2), hyperthyroidism (1), ulcerative colitis (2), recurrent pyrexia (1) and cœliac disease (2) The following case is an example of the findings in the majority of cases

Date	Daily dose of ascorbic acid	Ascorbic acid in urine	
		Before test dose	*3–5 hr after test dose*
		mg per 100 c cm	
April 11	None	0 15	None
,, 28	50 mg (ascorbic acid)	0 8	0 55
May 2–4	200 mg (in 3 days)	1 1	25 6
,, 13	40 mg (1½ oz b c puree)	13	55
,, 23	40 mg (1½ oz b c puree)	2 2	29 8
June 2	20 mg (¾ oz b c puree)	0 7	24

Age 6½ years weight 49 lb , admitted for investigation of state of lungs ? bronchiectasis

The difference in response to the test dose when saturation is attained is striking The ascorbic-acid content of the first specimen of urine before the test dose has very little value as an index of saturation, for unless an excess is being given, the urine contains little or no ascorbic acid

DISCUSSION

This experiment is only a preliminary survey and the conclusions reached are only approximately correct There are three sources of error, the first two of which we believe to cancel out the third The first is the variable amount of ascorbic acid taken in the diet—this has been assessed at 5 mg daily and ignored The second is the effect of the test dose given at irregular intervals, never less than 10 days and often as much as 21 days This would, of course, increase the minimal maintenance dose, but the amount cannot be calculated, as the excess over the saturation requirements is rapidly excreted , in effect this means that the subject starts every new test period freshly saturated and with an unknown but small amount of ascorbic acid in hand The third error is due to our inability to complete the full test in every subject by finding the level at which saturation is not maintained. In most cases, however, the response to the test dose was definitely smaller on the lower dose, indicating a decrease of the saturation level, and thus there was reason to consider that the minimal maintenance dose had been reached to within a few milligrammes

SUMMARY

Convalescent children in a children's ward were saturated with ascorbic acid Ascorbic acid in the form of black-currant puree was then given as a dietary supplement and the level at which saturation could be maintained was determined by the urinary response to a test dose of ascorbic acid The level of the daily dose was found to vary from 15 to 6 mg per stone according to age, corresponding to average daily doses of 1½–2 oz puree per child

Our thanks are due to Dr Janet Gimson and the ward sisters and staff for help in collecting the specimens, to Messrs Chivers for supplies of black currant puree and to Miss Mamie Olliver for some analyses and advice

LUPUS ERYTHEMATOSUS AND TUBERCULIN TESTS

JOHN KELVIN, M B LEEDS, L R C P E

THE ætiology of lupus erythematosus is still in dispute Some authorities regard it as always a tuberculide, some as always a result of focal sepsis, some think it may be either one or the other, some blame an undiscovered organism, and some suggest that the toxin of either the tubercle bacillus or a streptococcus has sensitised the skin to light This last explanation should mean that the condition is simply an actinic dermatitis If so, why should light produce the peculiar lesion of lupus erythematosus? And why should two entirely different organisms produce the same unique bizarre and—in general practice—rare lesion? It is easy to understand that different causative factors might produce dermatitis or erythema, but this lesion is distinctive Can more than one organism produce a gumma?

In my opinion lupus erythematosus is due to an innate characteristic of the skin, usually congenital but sometimes acquired, which renders it peculiarly susceptible to the action of mild tubercle toxin The action of the toxin is aggravated by irritation, which may be extrinsic (heat, cold, friction, injury or light), or intrinsic (sepsis or worry) The irritation produces a secondary specific toxin which actually causes the lesion and I believe this toxin to be of the nature of a mild slowly acting caustic

These opinions are based on the results of tuberculin testing in a series of 148 cases of lupus erythematosus (including 3 of the disseminated variety) and 240 people with healthy skins or other dermatological conditions All the patients, except one aged 14, were adults The results are shown in tables I and II In addition, simultaneous Mantoux and Lederle tests were carried out on 300 cases of miscellaneous dermatoses, including 6 tuberculides Of the 300, 61 (20%) gave a positive Mantoux test and 56 (19%) a positive Lederle test

TABLE I—RESULTS OF MANTOUX TEST IN 86 CASES OF LUPUS ERYTHEMATOSUS AND 140 CONTROLS

Strength of old tuberculin used	Lupus erythematosus		Controls		
	Cases	Positive	Diagnosis	Cases	Positive
1/100, 1/1000, 1/10,000	24	15 (62 5%)	Miscellaneous dermatoses	20*	8 (40%)
1/500 1/1000	17	14(82%)	,,	24	4 (16 6%)
1/1000	25	19(76%)	,,	32	5 (16%)
1/600 1/650 1/660, 1/700, 1/750	20	15(75%)	,, Psoriasis Tuberculides Healthy skin	34 10 10 10	5 (15%) 3 (30%) 6 (60%) 0
Totals	86	63(73%)	—	140	31 (21 5%)

* Including 2 tuberculides

It will be seen that altogether 105 of the 148 cases of lupus erythematosus gave a positive tuberculin reaction (71%), compared with 43 of the 240 controls (18%) Moreover, a tuberculous history—old tuberculous glands, healed phthisis, or tuberculosis in the family—was commoner among the cases of lupus erythematosus than among the controls In one patient the lesions of lupus erythematosus were seen alongside and merging into the tuberculous lesions of Bazin's disease other observers have reported them in association with lupus vulgaris

The incidence of sepsis was no commoner among the cases of lupus erythematosus than among the controls Moreover, sepsis is too common and lupus erythematosus too rare for sepsis to have any important ætiological significance On the other hand, where septic foci are found in cases of lupus erythematosus they might easily be primarily tuberculous foci in which secondary infection has obscured the picture I performed "septic" tests, analogous to the Mantoux test, in a small series of cases, but failed to demonstrate any increased sensitivity to the toxins of septic organisms Thus I tested 24 cases of lupus erythematosus with the toxins of three organisms, used separately—those of *Streptococcus hæmolyticus Strep viridans* and a staphylococcus Only one patient responded, giving positive reactions to *Strep hæmolyticus* and the staphylococcus Among 20 controls, too, only one patient responded, giving a positive reaction to the hæmolytic streptococcus but to neither of the other two organisms I then used a mixture of all three toxins on 16 other cases of lupus erythematosus, none of which gave a reaction, whereas there were 8 positive responses in a group of 48 controls

TABLE II—RESULTS OF LEDERLE (VOLLMER) TUBERCULIN PATCH TEST IN 62 CASES OF LUPUS ERYTHEMATOSUS AND 100 CONTROLS

Lupus erythematosus		Controls		
Cases	Positive	Diagnosis	Cases	Positive
—	—	Miscellaneous dermatoses	80*	12 (15%)
62	42 (67 7%)	Healthy skin	20	0
		Total	100	12 (15%)

* Including 2 tuberculides

Various causative factors have been suggested by different investigators, but countless people have one or more such factors operating strongly without developing lupus erythematosus Further, in other dermatoses alleged to be due to toxins—pemphigus, for example—the mucous membranes are affected, in lupus erythematosus the mucous membranes are rarely attacked primarily and I think this also points to an innate susceptibility on the part of the skin

In my view the ætiology of the condition has the following sequence —

Congenital predisposition → tuberculous toxin → some form of irritation → secondary toxin → lupus erythematosus

The endotoxin of the tubercle bacillus is incriminated rather than the bacillus itself because Koch's bacillus is not found in the lesions on microscopic examination, nor are tubercles present Light has been assigned a share in causation by some because the lesions of lupus erythematosus appear on exposed areas, these areas, however, are exposed to general and constant irritation from various factors including light, so that "exposed parts" can be taken to be synonymous with "irritated parts" Finally, it seems to me that only a substance with a cauterising action could produce the characteristic lesions and this I believe to be produced in the congenitally susceptible skin as a result of irritation

SUMMARY

A series of 148 cases of lupus erythematosus and 240 people with normal skins or other dermatological conditions were submitted to Mantoux or Lederle tuberculin tests, 71% of the lupus erythematosus cases gave positive reactions, compared with 18% of the controls

Tests analogous to the Mantoux test were performed with the toxins of three septic organisms—*Strep hæmolyticus*, *Strep viridans* and a staphylococcus—on

24 cases of lupus erythematosus and 20 controls Only one patient in each group gave a positive result When a mixture of all three toxins was used there were no positive results in 16 cases of lupus erythematosus, but 8 positives in 48 controls

It is suggested that lupus erythematosus is produced in susceptible people by the action of tuberculous toxin, extrinsic or intrinsic sources of irritation acting as secondary factors

PREVENTION OF DROPLET-BORNE INFECTIONS BY SPRAY

A FIELD EXPERIMENT

D. STEWART MIDDLETON,
M B EDIN, F R C S
COLONEL, A M S

I C GILLILAND,
M B EDIN
MAJOR, R A M C

INCREASING interest has lately been centred on the use of various methods designed to minimise the spread of infections, and the outbreak of war has stimulated research with a view to applying the results of laboratory observations to the treatment of crowded rooms and air-raid shelters The limitations of the laboratory experiments have been realised by Andrewes,[1] who in the summary of a recent paper says "We have discovered certain methods for the control of respiratory disease, none of these is of proved efficacy in the field, though all of them have given encouraging results in the laboratory" The necessary field experiments can be carried out most accurately under Service conditions, where large bodies of troops can be surveyed in strictly comparable conditions With this end in view we carried out such an experiment during the respiratory epidemic period of January–March, 1941

Two main conditions must be established for the statistical results to be of value First, the methods used must be so simple that there is a real likelihood of their being effectively carried out by the N C O s charged with the duty, and the materials used must be cheap and readily available, this prevents the use under Service conditions of the more complicated forms of spray and especially of the continuous electrically operated spray Secondly, a sufficiently large number of men, with an equal number of controls, all equally exposed to the introduction of infection from their contacts with the civil population, and all living under identical conditions of accommodation, clothing, diet and occupation, must be involved in the experiment The personnel of a searchlight brigade were selected as satisfactory subjects, for, with the exception of a few headquarters personnel occupying buildings, the men were all accommodated in huts under comparable conditions, receiving the same short home leave The brigade was widely dispersed over a mixed urban, mining and agricultural area of Scotland with fairly equal access to picture houses and other places of entertainment Thanks to the collaboration of Brigadier A H Morton and the regimental commanders the following arrangements were made

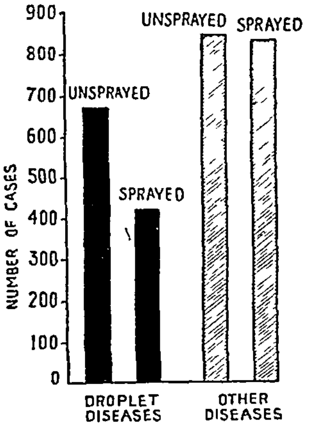

FIG 1—Total incidence of disease, Jan 5–April 6 1941

Twelve batteries were selected, each battery area adjoining that of its neighbours without any gaps between them Alternate batteries were sprayed over the whole area, leaving the intervening ones unsprayed Thus sprayed and unsprayed personnel were fairly evenly distributed over the segment of the British Isles involved By this means some 3000 men were subjected to spray with about an equal number of controls

Laboratory investigations have shown that hypochlorite solutions are effective in low concentrations Hypochlorite was easily accessible to the units in question in the form of th water-sterilising powder actually in use for the treatment o water supplies Simple intermittent spraying was therefor carried out in all huts, kitchens, messing rooms, &c with a approximately 1% solution of this bleaching powder Th spraying was carried out with the "Flit gun" variety o sprayer

Spraying batteries were instructed to spray every hut thrice daily—at reveille, on coming off duty in the late afternoon, and at lights out, these being the periods at which the greatest concentration of salivary droplets may be expected The Flit gun container was filled with water and a half scoopful of water sterilising powder added to it and shaken The N C O in charge then walked slowly round the hut spraying obliquely upwards towards the ceiling and continued to do so until the whole hut had a quite noticeable but not irritating odour of hypochlorous acid Complicated methods of control of dosage were clearly out of place and the exact strength of the spray varied because of differences in the construction of different makes of sprayer and deterioration of the solution which is often left in the gun and used again without being freshly made up The method of spraying to the limit of nasal tolerance for hypochlorous acid is both a simple and practical guide to the unskilled soldier

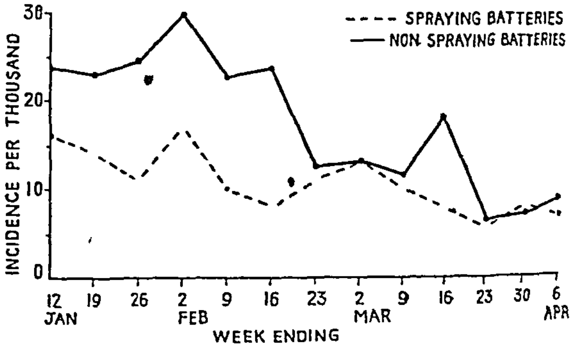

FIG 2—Incidence of droplet infections per thousand

The medical officers of both sprayed and unsprayed batteries completed a weekly return to the brigade senior medical officer showing (*a*) the ration strength of the battery for the week, (*b*) the number of men reporting sick on account of droplet infection, (*c*) the number of cases of sickness from causes other than droplet infections, and (*d*) the diagnoses of all cases of droplet infections All returns were then correlated by the brigade S M O and shown as incidence per 1000 personnel in sprayed and unsprayed groups The returns were corrected for variations in strength of batteries

RESULTS

During the period under review the total number of cases of droplet-borne diseases reporting sick in the sprayed community amounted to 425, compared with 670 in the unsprayed group The difference of 37% does not merely reflect a difference between the general sick-rate in the two groups, as is demonstrated by the fact that the non-droplet sick-rate in each is almost exactly the same, amounting to 834 in the sprayed and 850 in the non-sprayed (fig 1) A graph (fig 2) of cases of droplet infection in each week per 1000 personnel shows that the difference between sprayed and unsprayed groups is greatest during the period of maximum incidence of droplet-borne disease The curves meet at the end of the experimental period when epidemics of influenzal colds had died down It is significant that the outlines of the two curves follow each other fairly closely

There were no complaints of damage to clothing or metal parts of weapons by the bleach spray Sprayers of various makes but of similar design were used and it was found that some of them became unserviceable by rust on plungers and corrosion of containers The better, but not necessarily more expensive, type of sprayer has a piston and piston shaft constructed of rustless material The well-constructed container of galvanised iron which is associated with this will stand up to the corrosive effect of bleach solution for one season in most cases In the event of spraying being used on a large scale a non-corrodable material should be used

---

[1] Andrewes, C H *Lancet*, 1940, 2, 770

MODE OF ACTION

In an attempt to determine how the spray acts the assistance of Dr C. P. Stewart was enlisted and an apparatus was constructed to aspirate a measured volume of air (about 20 litres) through a solution of potassium iodide to detect chlorine by the liberation of iodine. The apparatus is capable of detecting 0·01 mg. of chlorine in the volume of air taken. The door and windows of the hut were closed and spraying carried out by the N.C.O. in the normal manner. The air drawn through five minutes later showed no detectable amount of chlorine in spite of the fact that a definite odour of hypochlorous acid persisted. It was observed that the spray droplets appeared to settle rapidly and to dry off on floor, walls and window ledges. Dust from these situations was accordingly tested with potassium iodide and starch and in every instance showed the presence of available chlorine. Later experiments under laboratory conditions showed that chlorine could be detected from the dust up to six hours after a single spraying. From these observations several modes of action may combine to produce beneficial results:

A sedimentation effect by spray droplets entangling and carrying down with them the smaller infected salivary droplets.

A direct sterilising effect on the organisms suspended in these droplets.

A further temporary effect in laying and sterilising organisms in dust on the floor.

A slow continuous action by the release of chlorine from the fine deposit of bleaching powder spread over the hut, persisting until renewed on the next routine spraying.

DISCUSSION

At first sight the 37% reduction in the incidence of droplet-borne disease in the sprayed groups looks significant but a detailed study of the figures from individual batteries makes it less convincing (see table).

INCIDENCE OF SICKNESS IN INDIVIDUAL BATTERIES CORRECTED FOR STRENGTH OF BATTERIES

SPRAYED			UNSPRAYED		
Battery	Non-droplet diseases	Droplet diseases	Battery	Non-droplet diseases	Droplet diseases
A	68	71	G	109	182
B	135	45	H	251	223
C	158	61	I	174	77
D	145	65	J	120	45
E	103	85	K	110	82
F	225	95	L	85	63
Total	834	425		850	670

It is evident that the figures for G and H Batteries in the unsprayed group are largely responsible for the apparent differences between the groups and that if these two batteries were neglected the incidences of droplet disease would be approximately the same in the sprayed and unsprayed group. The figures for G and H Batteries may be explained on one of the following hypotheses: (a) A local condition in the batteries concerned, such as a slack or over-conscientious medical officer, a poor level of general health, or low morale among the troops; or (b) an epidemic of catarrhal disease involving these two batteries. If any local conditions had been responsible the level of non-droplet sickness in these two batteries should have been correspondingly high. This is not so. H Battery, with a very high non-droplet and droplet rate, may usefully be compared with F Battery in the sprayed group which shows an almost equally high non-droplet rate with a reasonably low droplet rate. G Battery's non-droplet rate is not abnormally high and it is interesting to compare it with the figures of D Battery in the sprayed group. G and D Batteries belong to the same regiment, occupying adjacent areas of a strictly comparable rural type of country, without special exposure to infections. G showed a very high droplet rate while D, with a much higher general-sickness rate, had roughly a third of G's droplet rate. The conclusion is that the high incidence in G and H Batteries is the result of local epidemics of catarrhal disease. It is perhaps significant that two out of six unsprayed batteries suffered in this way while none of the sprayed batteries, even though in areas closely adjacent to the affected batteries, were involved.

SUMMARY

A controlled experiment using the most elementary and simple form of spraying with a hypochlorite solution affords some evidence that this method is capable of diminishing the spread of droplet-borne infections within a unit. The method achieves its best results during epidemic periods.

We are indebted to Major J. L. Cowan, R.A.M.C., for assistance in the earlier stages of the investigation and to the regimental medical officers of the brigade without whose coöperation this experiment could not have been carried out.

BIOPSY OF THE ENDOMETRIUM

JOHN HOWKINS, M.D., M.S. LOND., F.R.C.S., M.R.C.O.G.
RESIDENT ASSISTANT PHYSICIAN ACCOUCHEUR TO ST. BARTHOLOMEW'S HOSPITAL; SQUADRON LEADER R.A.F.V.R.
(*The Williamson Laboratory, St. Bartholomew's Hospital*)

For some years American gynæcologists have been obtaining biopsy specimens of the endometrium for histological examination without anæsthesia as an out-patient examination. In this country a small number of gynæcologists have adopted this practice and it is the purpose of this communication to put on record my experience of 238 biopsies in 84 patients over a period of a year at St. Bartholomew's Hospital in the hope that the safety and efficacy of this simple and convenient method of investigation may recommend it to others. The number of cases is not great since the war curtailed the work, but the figures are adequate for the conclusions drawn.

Most curettage operations are undertaken for purposes of diagnosis, but if exact information of the behaviour of the endometrium is to be obtained it is important that the curetting be done at a definite phase of the menstrual cycle. Pressure on hospital beds and the size of the waiting-list seldom allow of this exact timing, and often the bed is wasted and the patient is submitted to an operation the results of which are fruitless. Another small point is that the operation is often performed by a junior colleague or house-surgeon who does not know the exact reason for the curettage and who, from inexperience, may obtain a specimen—possibly from the isthmus or endocervix—which is inadequate for histological study. Endometrium most representative of the whole may best be obtained at the fundus, and after a little practice an operator of average dexterity will almost always procure his specimen from this region; moreover, he will know by inspection whether he has secured a useful piece or must explore a second time. In this way, always seeing the same cases and always operating himself, he is sure of the exact continuity of his specimens, which is essential in diagnosis and in the ultimate histological assessment of the results of any given endocrine therapy.

There are at present two methods whereby one may obtain exact information about a woman's menstrual cycle—by serial biopsy of her endometrium and by biological assay of her hormones either circulating in the blood-stream or excreted as end-products in her urine. The estimation of urinary pregnandiol is a good example of such biological assay, and its presence at a given time in a given quantity is at least presumptive evidence of ovulation and corpus-luteum formation. This evidence becomes more than presumptive if a biopsy specimen taken in the last week of a 28-day cycle shows an endometrium with well-marked secretory-phase changes in the glands and stroma. As a positive check on the efficacy and the dosage of hormone therapy endometrial biopsy is again extremely valuable, and in many cases in this series it has made it possible to demonstrate œstrogenic and secretory changes in the endometrium where a previous serial biopsy had shown them to be deficient or absent. The method must never be used in an attempt to diagnose malignant disease in the cavity of the uterus. Endometrial biopsy as performed on outpatients has considerable advantages from an economical point of view. An examination that would

24 cases of lupus erythematosus and 20 controls Only one patient in each group gave a positive result When a mixture of all three toxins was used there were no positive results in 16 cases of lupus erythematosus, but 8 positives in 48 controls

It is suggested that lupus erythematosus is produced in susceptible people by the action of tuberculous toxin, extrinsic or intrinsic sources of irritation acting as secondary factors

PREVENTION OF DROPLET-BORNE INFECTIONS BY SPRAY

A FIELD EXPERIMENT

D STEWART MIDDLETON,
M B EDIN, F R C S
COLONEL, A M S

I C GILLILAND,
M B EDIN
MAJOR, R A M C

INCREASING interest has lately been centred on the use of various methods designed to minimise the spread of infections, and the outbreak of war has stimulated research with a view to applying the results of laboratory observations to the treatment of crowded rooms and air-raid shelters The limitations of the laboratory experiments have been realised by Andrewes,[1] who in the summary of a recent paper says "We have discovered certain methods for the control of respiratory disease, none of these is of proved efficacy in the field, though all of them have given encouraging results in the laboratory" The necessary field experiments can be carried out most accurately under Service conditions, where large bodies of troops can be surveyed in strictly comparable conditions With this end in view we carried out such an experiment during the respiratory epidemic period of January–March, 1941

Two main conditions must be established for the statistical results to be of value First, the methods used must be so simple that there is a real likelihood of their being effectively carried out by the N C O s charged with the duty, and the materials used must be cheap and readily available, this prevents the use under Service conditions of the more complicated forms of spray and especially of the continuous electrically operated spray Secondly, a sufficiently large number of men, with an equal number of controls, all equally exposed to the introduction of infection from their contacts with the civil population, and all living under identical conditions of accommodation, clothing, diet and occupation, must be involved in the experiment The personnel of a searchlight brigade were selected as satisfactory subjects, for, with the exception of a few headquarters personnel occupying buildings, the men were all accommodated in huts under comparable conditions, receiving the same short home leave The brigade was widely dispersed over a mixed urban, mining and agricultural area of Scotland with fairly equal access to picture houses and other places of entertainment Thanks to the collaboration of Brigadier A H Morton and the regimental commanders the following arrangements were made

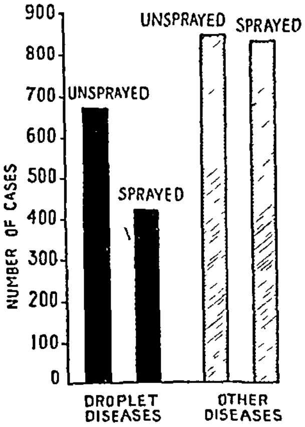

FIG 1—Total incidence of disease, Jan 5–April 6, 1941

Twelve batteries were selected, each battery area adjoining that of its neighbours without any gaps between them Alternate batteries were sprayed over the whole area, leaving the intervening ones unsprayed Thus sprayed and unsprayed personnel were fairly evenly distributed over the segment of the British Isles involved By this means some 3000 men were subjected to spray with about an equal number of controls

Laboratory investigations have shown that hypochlorite solutions are effective in low concentrations Hypochlorite was easily accessible to the units in question in the form of water-sterilising powder actually in use for the treatment water supplies Simple intermittent spraying was therefore carried out in all huts, kitchens, messing rooms, &c with an approximately 1% solution of this bleaching powder The spraying was carried out with the "Flit gun" variety of sprayer

Spraying batteries were instructed to spray every hut thrice daily—at reveille, on coming off duty in the late afternoon, and at lights out, these being the periods at which the greatest concentration of salivary droplets may be expected The Flit gun container was filled with water and a half scoopful of water-sterilising powder added to it and shaken. The N C O in charge then walked slowly round the hut spraying obliquely upwards towards the ceiling and continued to do so until the whole hut had a quite noticeable but not irritating odour of hypochlorous acid Complicated methods of control of dosage were clearly out of place and the exact strength of the spray varied because of differences in the construction of different makes of sprayer and deterioration of the solution which is often left in the gun and used again without being freshly made up The method of spraying to the limit of nasal tolerance for hypochlorous acid is both a simple and practical guide to the unskilled soldier

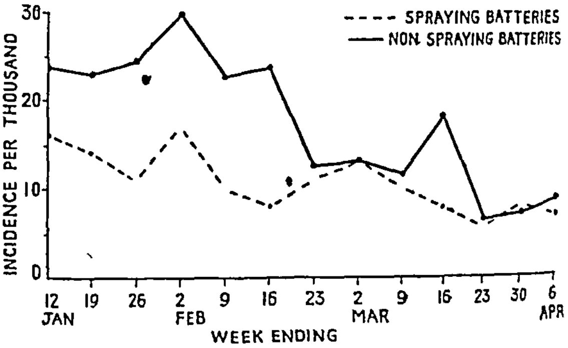

FIG 2—Incidence of droplet infections per thousand

The medical officers of both sprayed and unsprayed batteries completed a weekly return to the brigade senior medical officer showing (a) the ration strength of the battery for the week, (b) the number of men reporting sick on account of droplet infection, (c) the number of cases of sickness from causes other than droplet infections, and (d) the diagnoses of all cases of droplet infections All returns were then correlated by the brigade S M O and shown as incidence per 1000 personnel in sprayed and unsprayed groups The returns were corrected for variations in strength of batteries

RESULTS

During the period under review the total number of cases of droplet-borne diseases reporting sick in the sprayed community amounted to 425, compared with 670 in the unsprayed group The difference of 37% does not merely reflect a difference between the general sick-rate in the two groups, as is demonstrated by the fact that the non-droplet sick-rate in each is almost exactly the same, amounting to 834 in the sprayed and 850 in the non-sprayed (fig 1) A graph (fig 2) of cases of droplet infection in each week per 1000 personnel shows that the difference between sprayed and unsprayed groups is greatest during the period of maximum incidence of droplet-borne disease The curves meet at the end of the experimental period when epidemics of influenzal colds had died down It is significant that the outlines of the two curves follow each other fairly closely

There were no complaints of damage to clothing or metal parts of weapons by the bleach spray Sprayers of various makes but of similar design were used and it was found that some of them became unserviceable by rust on plungers and corrosion of containers The better, but not necessarily more expensive, type of sprayer has a piston and piston shaft constructed of rustless material The well-constructed container of galvanised iron which is associated with this will stand up to the corrosive effect of bleach solution for one season in most cases In the event of spraying being used on a large scale a non-corrodable material should be used without a rest period If this dose is adjusted for body-weight it represents less than half the doses suggested by Manson-Bahr for adults and children

---

[1] Andrewes, C H *Lancet*, 1940, 2, 770

Phenothiazine was sent to me by Dr C M Scott for clinical trial and I have used it, in a preliminary investigation, in 8 children In one of these (case 1) poisoning occurred

CASE 1—Girl, aged 12 years Weight 78 lb Referred from the school clinic for treatment of threadworms on July 3, 1941 Phenothiazine 4 g for seven days prescribed On July 10 the child was jaundiced with a furred tongue Her mother stated that for three days she had been ill, her chief symptoms were nausea, anorexia, insomnia and depression On July 17 jaundice had faded, but she was obviously anæmic and a blood count showed red cells 2,900,000 Hb 60%, white cells 8900 per c mm, neutrophils 44% (3916), lymphocytes 53% (4717) and monocytes 3% (267) On the 24th, after a week's treatment with iron, a blood examination showed red cells 3,330,000, Hb 68%, C I 1 02, average diameter of red cells 7 6 μ, white cells 4300, platelets 300,000, volume of packed red cells 36 9% of blood volume, mean corpuscular volume 110 8 c mm (normal 78–94 c mm, average 86 c mm), eosinophil polymorphs, 2% (86), monocytes 2 5% (108), lymphocytes 50% (2150), neutrophil polymorphs 45 5% (1956), neutrophil nuclear index

Patient i, 46, ii, 46, iii, 8, iv, 0, v, 0
Normal 12 25 25 15 4

Red cells show little variation in size and shape, no stippled or nucleated reds seen, reticulocytes number about 10% of the red cells

Urine—Acid, no albumin, no sugar, microscopically clear, no blood pigments &c, present Van den Bergh negative

Complete recovery occurred in one month from the onset of symptoms

The effects of phenothiazine poisoning in this child were shown by the anæmia and jaundice It is improbable that the jaundice was hæmolytic in origin, since the anæmia was not sufficiently profound for this, moreover, the clinical condition of the child was strongly suggestive of a hepatitis This toxic effect on the liver has not been previously reported, but it might have been forecasted in view of the chemical structure of phenothiazine It is well known that substances containing benzene, such as trinitrotoluene, dinitrobenzene, dinitrophenol and arsenobenzene derivatives, are poisonous both to the liver and the blood elements As has been suggested above, no help in the differential diagnosis of the jaundice can be expected from the van den Bergh test, which gives an invariable positive indirect reaction when phenothiazine is being taken The blood-picture in this child showed a severe degree of anæmia and a leucopenia, with evidence of active hæmopoiesis in red cells and neutrophils

Of the other patients treated with phenothiazine, blood examinations were made before and after treatment in 2 and in one there was evidence of a moderate anæmia

CASE 2—Boy, aged 5 years Weight 38 lb Referred from the school clinic for treatment of nocturnal enuresis on July 24, 1941 He was found to be suffering from threadworms also His blood examination made before treatment with phenothiazine showed red cells, 4,600,000 per c mm, Hb 83%, reticulocytes less than 1%, eosinophils 2000 per c.mm He was given 0 5 g phenothiazine three times a day for a week. Blood examination then showed red cells 4,000,000, Hb 72%, C.I 0 9 average diameter of red cells 7 6 μ, white cells 7000, platelets 200,000, cell volume 37 5% of blood-volume, mean corpuscular volume 93 75 c μ Red cells show relatively little variation, about 3% are reticulocytes Eosinophil polymorphs 13% (900), neutrophil polymorphs 33% (2320), lymphocytes 51% (3570), monocytes 3% (210)

Urine—Some epithelial cells Very few leucocytes present No threadworms were seen after four days' treatment, but eosinophils were still high at 900 per c mm

Judging by the American series quoted above, poisoning may be expected in a fair proportion of cases if a total dosage of more than 15 g is administered to adults This does not include instances of idiosyncrasy which have not yet been reported but which may be expected to occur rarely Since evidence of poisoning was discovered in 2 of these 8 children, I decided to assess total dosage in future by body-weight Accepting the American standard of 15 g for an approximate weight of 150 lb, 1 g for every 10 lb of body-weight was used as the total dose This amount was spread over 3–5 days and if the threadworms had not entirely disappeared a second course was given a week later More than 20 children were thus treated, several of them required the second course but all of them were declared by their mothers to be free of threadworms One child was stated to be depressed and another off her food while under treatment No further evidence of toxicity was discovered until the last case of the series

CASE 3—Girl, aged 2½ years Referred from the school clinic for treatment of threadworms Weight 29 lb Phenothiazine 1 g for three days prescribed On the second day of treatment the child was sick and lacked appetite, on the third day the mother noticed that the child was yellow The next day, on examination, jaundice was confirmed, the liver was enlarged to just above the umbilicus and appeared tender the urine was red with the excreted dye Blood examination on the fifth day showed red cells 41,200,000, Hb 75%, C I 0 89 average diameter of red cells 7 55 μ; white cells 9300, platelets 400,000, eosinophil polymorphs 7%, basophil polymorphs 0 3%, neutrophil polymorphs 24 3%, lymphocytes 63% (5859), monocytes 5 3% (493), neutrophil nuclear index Patient *1*, 62, *2*, 30, *3*, 8, *4*, 0 *5* 0 Normal *1* 12 *2*, 25, *3*, 44 *4* 15 *5* 4

A week later the child's general health had improved; her appetite was normal and the liver was smaller but the conjunctivæ were still bile-stained This child's blood showed a mild anæmia with moderate stimulation of hæmopoiesis She was undoubtedly suffering from a toxic hepatitis

EFFICACY OF PHENOTHIAZINE

The employment of a potentially toxic drug in the treatment of a comparatively trivial infestation requires justification Although trivial infestation by oxyuris vermicularis is very common, large-scale investigations in lower and middle class white children in Washington D C gave a 50% incidence in children from six to eighteen years of age No comparable investigation has been made in this country, it is a formidable research, because routine examinations of fæces are without value and the eggs have to be sought in peri-anal smears The ordinary clinical standard of cure is a statement by the mother that she can no longer see threadworms in the child's fæces This standard is frequently shown to be faulty by the re-emergence of threadworms, sometimes years later Assessed even by these standards, the uniformly effective drug has not yet been discovered. Hexylresorcinol, as employed in an elaborate technique by Brown (1932), gave complete success judged by the highest standards Wright and Brady (1940) obtained 60–90% cures in adults and children with gentian violet by mouth It is probable that Butolan and its more recent equivalents which have been widely used in this country have a comparable efficiency with gentian violet

It is unfortunate therefore that phenothiazine which appears to be completely successful in the treatment of threadworms should sometimes be toxic to the host even in small doses Consideration of case 3 suggests that it will be wise in future to restrict its use to cases where less dangerous therapies have repeatedly failed Its administration should then be strictly supervised

SUMMARY

Phenothiazine has been shown to be an effective remedy against threadworms in more than 30 cases

Phenothiazine is poisonous to the blood and the liver in much smaller doses than have been suggested for the treatment of threadworms Three cases of anæmia following its use have already been recorded in the literature and 3 further instances are given here In 2 children it also produced a toxic hepatitis

Phenothiazine is probably too dangerous a remedy to be used in the routine treatment of threadworms

I am grateful to Dr G R Osborn, pathologist to the hospital, for the pathological investigations recorded and to Dr C M Scott, of Imperial Chemical Industries Ltd, who supplied me with phenothiazine

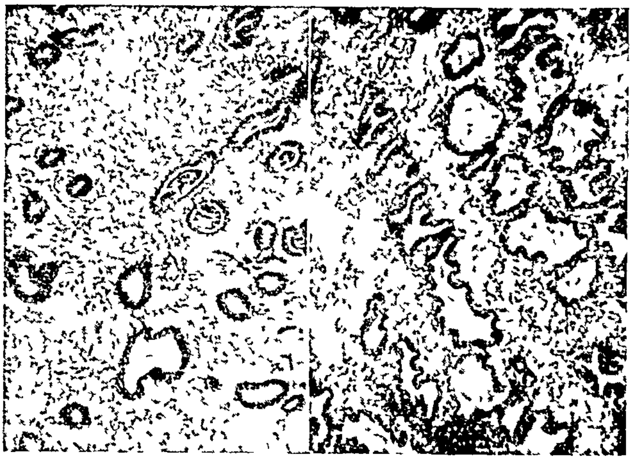
entail the use of a hospital bed for a month, and immobilise a woman who may be extremely unwilling to leave her family or her job, can be carried out in this way equally well and perhaps better without admission to hospital, crowded gynæcological waiting-lists are thus kept free for the more urgent hysterectomies and prolapses

TECHNIQUE AND RESULTS

The present series consists of 84 patients 44 cases of sterility, 31 cases of irregular uterine bleeding and 9 cases of amenorrhœa The total number of biopsies performed in these women was 238, the average number being 2 or 3 in each case and the highest individual score 10, several had 5, 6 or 7 biopsies



(a) (b)

Biopsy specimens of endometrium (a) Œstrogenic, (b) secretory phase

The technique is simple At the first examination a careful history is taken and the menstrual cycle should be plotted on a printed menstrual history case sheet A bimanual pelvic examination is made and a vaginal speculum passed, the cervix being inspected to exclude any organic lesion Any cervical infection is best treated and eliminated before the performance of endometrial biopsy If the case is suitable for biopsy the patient is asked to attend on the day chosen with reference to her menstrual chart, and it has always been my practice to explain what the examination entails and the reasons for it, thereby ensuring the patient's cooperation and confidence No shaving of the vulva and perinæum is necessary, but the patient is instructed to have a bath on the morning of operation after cutting the pubic hairs reasonably short When the biopsy is to be taken she is placed in the lithotomy position, the vagina and cervix are well cleaned and the vagina swabbed out with Dettol The operator should wear a mask, gown and rubber gloves, which are kept in a special drum in the outpatient clinic A small Auvard's speculum is introduced and the sister retracts the anterior vaginal wall if necessary The cervix is grasped with light fine volsella and gently steadied, and a small malleable sound is passed to ascertain the direction and size of the cervical canal, occasionally this is narrow and one or two small dilators may then be passed A fine sharp curette is introduced and a specimen of endometrium obtained from the fundus

With practice, the whole proceeding takes only a few minutes and the quicker it is done the less likely is the patient to be worried by it No special instruments are required and in all these cases a small fine ethmoid curette was used and proved itself a trusty and efficient instrument No special suction curette was ever used All the instruments are sterilised by boiling for each case, and if the pressure of work is severe they can be duplicated to save time After the examination the woman is sent to dress and always interviewed before she leaves hospital to make sure that she is feeling no ill effects She is also warned to expect a faint show for 24 hours or so and assured that this is normal

The pain experienced varies in different women The cervix, like most hollow viscera, can be cut and burned by the cautery with relatively little discomfort in the conscious patient, but she rather resents it being stretched The passage of a dilator is usually c[illegible] on and in some cases complained of as painful, th[illegible] seldom as severely so, hence it is important to use a small instrument In two of my cases both nulliparæ, it was impossible to pass an instrument into the cervical canal and these cases had perforce to be put on the inpatient waiting-list Needless to say, unmarried or virgin patients are as a general rule unsuitable for biopsy without hospital admission Considering the series as a whole, pain and discomfort during the operation provided a contra-indication in very few patients Of other minor ill effects, one patient had a mild syncopal attack and nearly fainted and one was sick These symptoms occurred in the earlier cases, with increasing experience and dexterity untoward effects were rare

In assessing the value of this method of investigation the main criterion is the histological information obtained A biopsy specimen may be said to be satisfactory if it contains a fair-sized piece of endometrium showing the stromal and glandular pattern clearly, so that study of it will definitely place the endometrium in a given category—typically œstrogenic (fig a) or typically secretory (fig b) With a good section there will be no doubt or hesitation in so placing it In this series 210 of the 238 specimens were classed as good, 18 as adequate, and 10 as useless In this last class are included those sections which contained no endometrium, or only cervical mucosa There is a notable improvement in the proportion of good specimens among the later cases of the series and this is of course the result of practice

SUMMARY

Biopsy of the endometrium has been performed 238 times in 84 outpatients

It is a simple and safe procedure that can be conducted without anæsthesia or premedication and without remarkable discomfort to the patient

The technique used is described, it requires no special instruments and only average skill on the part of the operator

Judged from a histological standpoint, the specimens obtained provided the information required in all but 10 out of a total of 238

Biopsy of the endometrium provides exact knowledge of the functional state during any given menstrual cycle, and is particularly useful in cases of sterility and irregular uterine bleeding It also enables a check to be made on the results and dosage of hormone therapy

It allows of a great saving of time and money to patient and institution

I wish to thank my seniors at St Bartholomew's Hospital, Dr Malcolm Donaldson, Dr Wilfred Shaw and Dr John Beattie for their help, and Mr B Cambridge, for cutting and staining all the sections

---

TOXICITY OF PHENOTHIAZINE

DOUGLAS HUBBLE, M D LOND
PHYSICIAN TO THE DERBYSHIRE HOSPITAL FOR SICK CHILDREN

THE use of phenothiazine (thiodiphenyl-amine) in the treatment of threadworms was first suggested by Manson Bahr (1940) He recorded successful results in 6 children and 3 adults, and advised that children under four years should be given 1 g daily for seven days, children between four and eight 2 g daily for seven days, and adults 8 g daily for at least five days de Eds, Stockton and Thomas (1939), who have investigated the pharmacology of phenothiazine, reported that out of 19 patients in whom blood-counts were made before and after medication with phenothiazine, 3 developed an anæmia These 3 patients had taken a total dosage of 22 4, 28 1 and 19 9 g respectively, in the third patient the red-cell count dropped from 4,410,000 to 1,570,000, with reticulocytes increased to 35% No toxic effect on the leucocytes was observed They discovered no undesirable effects from the drug in the gastro-intestinal tract, kidneys or liver The 11 patients on whose serum the van den Bergh test was done all showed a positive indirect reaction, this reaction was attributed to the colour of the dye in the blood-serum They recommend that, in view of its effect on the red cells, the maximum total dose of phenothiazine should not exceed 15 g used. Bacteriological surveys often revealed defects in dressing technique. Professor Miles said he had made an investigation, with Dr Joyce Wright, of the incidence of cross-infection in a ward containing both air-raid casualties and operation cases; during the first period an ordinary dressing technique was used, and during the second the team-technique was used, masking was compulsory, and there was a quiet period in the ward before dressings were begun. Results were as follows:

	Air raid casualties	Cross infection	Operations	Cross infection
1st period	32	10	46	2
2nd „	46	1	49	0

In both periods 10 heavily infected cases were admitted, so that the menace was about the same; but the revision of technique reduced cross infection from about 15% to 1%. Improved aseptic precautions did not entail an increase of medical or nursing staff, and the speed of teamwork made up for the time lost by employing several people on one dressing. More bacteriologically controlled surveys were needed to test the effect of prophylactic methods, and to establish that cross infection was important even in wards where its effects were not obvious.

Prof J Paterson Ross remarked that this "fiddle-faddle" of aseptic technique—as Clifford Allbutt had called it—must be attended to. Simple precautions could be taken against dust and droplet-infection by shutting windows and stopping bedmaking an hour before dressings were due to begin. Receptacles containing dressings should have lids to them, and the wound must be left uncovered for the minimum time. Masks must be not only impervious but large enough to cover the nose and chin and stretch a good way to the sides; they should measure 6 × 8 in at least. In order to prevent contact infection forceps should be used or gloves worn; hands and instruments should be dry, and the fingers of the dresser should never touch the wound, the skin round it, or the dressings next the skin. Palpation round the wound could be done, if necessary, with a piece of wool held in the forceps; and where it was impossible to dress a wound entirely with forceps—as might happen with an empyema wound—the patient should be taken to the theatre and dressed with full theatre technique. In the wards separate packets of dressings might be used for each patient and opened with forceps on a sterile towel spread on the top of the trolley; the dresser could then take what he needed instead of having it handed to him, and the clean trolley attendant need only hand him the sterilised instruments. All instruments should be boiled; the edge of a cutting instrument was not spoiled if it was properly wrapped while boiling. Two minutes in boiling water sufficed if instruments had been properly washed. Bowls and irrigating cans should be immersed during boiling. Antiseptic solutions should be checked to see whether they were used strong enough and long enough; spirit could not be trusted. These methods were neither new nor elaborate; they were merely a revival of aseptic technique. It was well to try to oil floors and treat blankets to prevent the spread of dust, but if these measures were not practicable surgeons must make sure that dressing drill was properly learned. The wound which failed to heal by first intention was more liable to cross-infection. It was unreasonable, he said, to use a good technique in the theatre, and a bad one in the ward. In outpatient departments, too, all the rules were broken. Surgeons must teach their students that the quick glance at a wound was dangerous, inviting droplet infection. Indeed, any removal of the dressing was dangerous. He thought that in future we must look forward to a special dressing-room opening off the ward. The tendency was to dress wounds too often, as closed-plaster technique had shown. But it must not be forgotten that organisms could get in and out of plaster, and could be disseminated when a plaster was changed. The Medical Research Council memorandum No 6 suggested that an asepsis officer should be appointed in large hospitals, but Professor Paterson Ross felt that the surgeon in charge of a unit must be responsible for the technique in that unit; he could always count on help from the bacteriologist. To achieve an aseptic conscience was better than being shadowed by an aseptic policeman.

Dr M van den Ende held that in general surgical wards cross-infection of wounds occurred mainly through contact, and a careful dressing technique would reduce the incidence. In ear, nose and throat wards, or scarlet-fever wards, the upper respiratory tract was of course more liable to be the source of infection. This region, which trapped bacteria from more than 10 cu ft of air per hour, was specially likely to harbour organisms if it had recently been the site of an operation. We were not yet clear, he said, about what constituted a danger. If one streptococcus was enough to produce a cross-infection then dust was dangerous; if 1000 streptococci were needed that danger was slight. But there was danger of dissemination by droplets even in a general surgical ward. The nurse with an upper respiratory infection should be sent on leave. Patients with such infections had been shown to deposit large numbers of organisms on the bedclothes near the head, and these were disseminated during bedmaking. Photographs of sneezers showed the distant projection of droplets, and gauze masks might not intercept these. Cellulose-acetate masks should therefore be used. Large droplets carrying infective doses had a relatively short range and fell to the ground rapidly; adequate bed spacing and masking dealt with them effectively. During dusting and bedmaking the number of organisms in the air of a ward were at their peak, and they could remain suspended for long periods. Treatment of the floors and bedclothes with dust-laying oils reduced the numbers successfully. For 1000 sq ft of floor 1 gallon of spindle oil was needed. It looked dull, but the nurses got used to it, and if the excess was removed it was not slippery. It was not bactericidal, and no suitable antiseptic had yet been found to mix with it, but efforts were being made to find one. Technical white oil could be used for bedclothes, and could be applied in the hospital laundry. He thought that tests were urgently needed of the value of dust-laying methods in reducing cross-infection, especially in scarlet fever, diphtheria and ear, nose and throat wards.

Colonel Leonard Colebrook described two cases in which a general infection had been acquired from dust. He then traced the events following admission to hospital, in January, 1941, of a patient with severe burns infected with a type 12 streptococcus which was resistant to sulphanilamide. He was nursed in a bathroom 18–19 yards away from the ward first affected, and he ultimately died. Subsequently 14 cross-infections from his organism were identified, in 6 of which skin grafts were lost or went wrong as a result, while in the remainder there was infection of healing wounds, delayed healing or cellulitis. Every effort had been made to check spread—floors had been oiled and gloves and masks worn. The fact that the organism was sulphonamide resistant might have been partly responsible, and it might have other properties which made it particularly invasive. There had been hardly any acute throats in the affected wards. He believed that cross-infection was a bacteriological problem and should be dealt with by bacteriologists, and he favoured the idea of an asepsis officer, believing he could succeed in getting the facts over to students and nurses. If it was left to the surgeons there would be spurts of enthusiasm followed by lapses. It would be better to begin by having imperfectly trained asepsis officers than none at all. They should take the nurses into the laboratory and let them make cultures and learn a little first-hand bacteriology; their interest was a revelation.

Sir James Walton reminded the meeting that in this war we had had practically no experience of gross infections, Patients with bomb lacerations were operated on as soon as they got over the shock; their wounds were treated with sulphonamide and left for ten days, when they were found to be healing with clean granulation tissue. But if war came into this country we should see gross infections. Every medical officer must learn to adapt himself to what he could get. It was possible to dress wounds entirely without touching them, and thus without washing between cases. A man could not dress 40 cases, washing between each; but he could go round with forceps, using a separate packet of dressings and freshly sterilised instruments for each patient and never touch a wound. He had been inspecting many hospitals and had found none where dressing with forceps was compulsory. Ear, nose and throat cases should not be nursed in general surgical wards.

INSULIN HYPOGLYCÆMIA

CHANGES IN NERVOUS MANIFESTATIONS

R. D. LAWRENCE, M.D. ABERD., F.R.C.P.
PHYSICIAN IN CHARGE OF THE DIABETIC DEPARTMENT, KING'S COLLEGE HOSPITAL

CHANGES in the symptomatology of insulin hypoglycæmia in diabetics commonly occur as years of treatment go on and insulin reactions may differ so much from the original ones that patients are dangerously unaware of their onset. At first it is almost the rule that patients feel and easily recognise minor premonitory symptoms. These can be ascribed mainly to reactions of the *autonomic nervous system* and are akin to the effect of a dose of adrenaline; indeed they are probably due to an extra secretion of adrenaline produced in an attempt to mobilise stored glycogen into blood-sugar. Such symptoms are general weakness and faintness, tremors, sweating, hot or cold feelings and palpitation. Other early symptoms, less easily explained by hyperadrenalinæmia, are hunger pains, visual disturbances including diplopia, and tinglings, especially of the lips and tongue. Such symptoms occur, if at all, at definite times of the day or night, at the period of maximal insulin action, and are easily recognised and removed by eating 1–3 lumps of sugar. Many conscientious patients even welcome such mild attacks occasionally, regarding them as a sign that their diabetes is well controlled. Such symptoms indicate as clearly as an exact estimation that the blood-sugar is between 50–70 per mg. 100 c.cm. Should such symptoms be unrecognised or neglected, so that glycopenia persists for a long time, symptoms develop which may be classified, roughly at least, as being due to disturbed function of brain and *central nervous system*; these are mental confusion, symptoms exactly simulating alcoholic intoxication, muscular twitchings, convulsions, epileptiform seizures, transient hemiplegias and complete coma. All these effects disappear rapidly, and usually completely, on restoration of the blood-sugar; but they occasionally persist longer, especially if hypoglycæmia has lasted for one or more hours, and, very occasionally, there is permanent hemiparesis or mental impairment with definite histological changes in the nerve-cells. A few patients never feel early premonitory symptoms but experience the more serious group of symptoms from the start; yet considering the large number of stupid or careless patients on insulin treatment, serious attacks and sequelæ are exceedingly rare.

As years of insulin life go on, sometimes only after 5–10 years, I find it almost the rule that the type of insulin reaction changes, the premonitory autonomic symptoms are missed out and the patient proceeds directly to the more serious manifestations affecting the central nervous system. This applies to diabetics who have been continuously on unmodified soluble insulin as well as those who have been changed to protamine insulin, whose different, slower and more prolonged action often modifies the type of reaction. The following are typical of the changes I refer to. A patient, instead of becoming shaky, sweating, or hungry if his meal is unduly late, becomes suddenly confused and obstreperous, creates a scene and refuses sugar. Another, accustomed to drive a car and usually warned of hypoglycæmia by slight diplopia, becomes suddenly wild and unbalanced in his driving. Yet another, instead of being wakened at night by violent palpitations—his warning to take sugar—goes straight into convulsions and awakens so paralysed that he cannot reach his sugar. The same patient may at one time experience early premonitory symptoms and at another be quite unaware of an impending attack. It is obvious that these are serious dangers.

I can offer no satisfactory explanation of this change of symptomatology and the common failure of autonomic warning symptoms as time goes on. I have noticed how, at the beginning of insulin treatment, patients feel hypoglycæmia symptoms at a higher blood-sugar level—90 to 120 mg. per 100 c.cm.—than later on, when they may not experience the same feelings until the blood-sugar is 40–60 mg. per 100 c.cm. Here we may say that the tissues become attuned to a lower level of sugar concentration. But the condition I refer to occurs in patients who are often hyperglycæmic and only rarely hypoglycæmic. It is no mystery that if the blood sugar is low for long enough the central nervous system should react in some untoward way, because if sugar is, as we believe, the only fuel it can use the absence of this fuel must interfere with its vital function. It is also known that the higher cortical functions and centres suffer first and most severely, and that the function and anatomy of the basal ganglia and vital centres are rarely affected. But none of these facts explains why symptoms of upset of autonomic type fail to give warning of trouble as years go on.

I know of no way by which the original sensitivity of the autonomic nervous system can be re-established and the danger of serious hypoglycæmia entirely prevented, but certainly the urine in such diabetics should never be made continuously sugar-free throughout the 24 hours. If they are sugar-free at the time of minimal insulin activity—say after breakfast—they run an almost certain risk of hypoglycæmia at the period of maximal insulin action a few hours later. The most certain way of avoiding trouble in such cases is to give regularly a large carbohydrate buffer (20–30 g. of carbohydrate) before these times of intense insulin action, to anticipate and prevent hypoglycæmic attacks. With soluble insulin this carbohydrate should be given 3 hours after each injection; with protamine insulin it should be given at tea-time if the interval between lunch and supper is a long one, and in all cases at bed-time.

Medical Societies

ROYAL SOCIETY OF MEDICINE

AT a meeting of the Section of Surgery on Nov. 5, with Mr. E. ROCK CARLING, the president in the chair, a discussion on

Streptococcal Cross-infection in Wards

was opened by Prof. A. A. MILES. Such infection, he said, was an established phenomenon, but seldom gave rise to severe and fatal infections. The common results were cellulitis, erysipelas, extension of wound infection, delayed healing or failure of skin grafts. Of the bacteria commonly taking part *Streptococcus pyogenes* was most easily traced; and though not the commonest cross-infecting organism it was the most important because of its pathogenicity. The incidence of streptococcal cross-infection depended on sources of infection in wounds and upper respiratory passages, on the possible channels of infection, and on the state of the exposed tissues. In the surgical ward of peace-time, the streptococcal reservoir was mainly in the upper respiratory passages, and striking cases of infection were rare. In war-time, wounds infected before admission provided additional reservoirs, and hospital infection was commoner because of this and because of the greater susceptibility of the war wound compared with the operation wound. Poor accommodation and hastily trained staff also played their part. Peace-time technique might prove inadequate to meet the added risks of war. Infection could reach the wound by three main channels—dust, droplets, and transference of organisms on hands and utensils. These possible channels of infection demand separate precautions which Professor Miles divided into those associated with the actual dressing technique, and others. Among the latter were the use of impermeable masks to prevent droplet-infection, and the exclusion from the ward of anyone with an infected hand or finger. Common utensils should be disinfected every time they were used by an infected patient, and all his things should be kept separate, as far as possible, from those used by other patients. His wound should always be kept covered between dressings. There should be a quiet period in the ward before dressings were begun; bedmaking should cease so that dust could have time to settle. The dressings themselves should be carried out by a team consisting of a trolley attendant who had nothing to do with the patient but simply handed out sterile materials with forceps; a dresser, who used a “no-touch” technique; and an assistant. The dresser and assistant treated each case as a separate unit, washing their hands and having the instruments freshly sterilised between each dressing. They should, if possible, wear fresh dry gloves for each case; the wet scrubbed hand, with infection trickling down from the forearm, should not be

THE LANCET

LONDON   SATURDAY, NOVEMBER 15, 1941

WHAT'S IN THE NATIONAL WHEATMEAL LOAF ?

WHEN the Medical Research Council drew up its second memorandum[1] on national flour in the spring of 1941 it offered the nation something new Never before had knowledge been sufficient to select with confidence a loaf which would look and taste almost like white bread and yet contain such a large share of the best nourishment of the whole wheat grain The Medical Research Council s specification was definite, and if it had been adhered to and the new loaf had appeared simultaneously everywhere, uniform in character, attractive in appearance and easy to get, and if, just before and during its appearance, an earnest and urgent propaganda campaign had been undertaken, there can be no doubt that it would have found wide acceptance At least all those people who could be reached through their sense of duty to promote their own health and that of others, or to protect the lives of our merchant seamen, would have responded Many others would have tried the loaf through curiosity and if the loaf had been palatable would have continued to do a duty found not so unpleasant after all

Unfortunately, the national wheatmeal loaf was not launched in this way The millers did not produce the flour to any uniform specification, the bakers often baked it badly or not at all, and many retailers did not stock it and showed no interest when asked about it The Government propaganda was feeble Finally, on Aug 27, 1941, the final blow was struck in one of the Statutory Rules and Orders of the Ministry of Food,[2] which gave the following definition

> " National wheatmeal " means flour produced in the United Kingdom and consisting of 85% by weight of any of the products of the milling of clean wheat, provided that the remaining 15% of the products of that milling are the substances commercially known as fine wheatfeed and straight run bran , and includes any such flour to which has been added any substance authorised by the Minister to be an ingredient of national wheatmeal "

This definition makes no fine distinction as to selection of the most nutritious parts of the grain, and permits 85% national wheatmeal to consist of white flour with added bran A glance at the interior of the national wheatmeal loaf as baked in some parts of the country suggests that this is indeed the case The Medical Research Council, in making their definition of 85% national wheatmeal, chose two special safeguards the flour was to contain not less than one International Unit of vitamin B per gramme and less than 0 9% of fibre These two criteria neatly set the limits within which the composition of the flour should fall The first would prevent the flour being too white (too much refined) , the second would exclude the coarse bran and prevent the flour from being too dark and containing too much roughage This second criterion is the one which safeguards the interests of those who prefer the taste of white bread It is the bran which contributes the high fibre content, it is the bran whose taste is disliked by those who do not care for brown bread, and it is the bran which imparts the unpopular dark colour and coarse texture Investigation of the national wheatmeal loaf, as now supplied, has shown that the loaf which is disliked is the one of high fibre content This loaf is becoming more and more the rule , the national wheatmeal loaf is steadily deteriorating and consequently disappearing The flour in such national wheatmeal loaves of poor quality is said mostly to come from the few large milling concerns whose representatives claimed that the Medical Research Council's specification for 85% flour would put too great a strain on the small miller Actually, it seems, the small millers, whose voices are not heard, have made a more loyal effort in the country's interests

In this conflict between the national and individual interests the millers have thus won the day, and a golden opportunity of furthering the health of the people has been lost The situation of the national wheatmeal loaf after this defeat is now strategically bad but is it irremediable ? A good loaf, made to a strict specification and supported by wise propaganda, might still achieve victory

T N T

THE internal combustion engine and the high explosive, trinitrotoluene, belong to the category of doubtful benefits which scientific progress has given to the world, and the doubt is more than doubled when they come together in a bombing aeroplane T N T has gained great popularity as an explosive since it was first made in the laboratory by HEPP in 1880 and since its adoption by the German military authorities in 1902 As a blasting powder in peace-time it was used for its excellent properties of high stability as an explosive and low toxicity for human beings It can be hammered or turned in a lathe without exploding, and from the pharmacological point of view the toxic and lethal doses are relatively enormous Indeed PROSSER WHITE [1] in 1901 showed that dinitrobenzene was more poisonous to animals than trinitrotoluene, and he said that in some factories T N T had been substituted for D N B with great advantage to the health of the workers This was the attitude towards T N T up to the onset of the war of 1914–18, and paradoxically the " safe " properties of the explosive, because reliance was placed on them, led to a great deal of mischief in the form of poisonings and accidental explosions In the peace-time manufacture and handling of T N T little trouble is experienced but when war comes the demand for the explosive is enormous, many more workers are exposed to it, longer hours are worked, production is speeded up, new factories are built or adapted, and engineering and managerial skill becomes diluted It is then that poisoning from T N T becomes a major problem, as was well shown by our experience during the last war

The first fatality attributed to poisoning by T N T was in February, 1915, and LEGGE [2] describes how at the autopsy he was struck by the jaundice of the sclerotics and skin resembling that seen in poisoning by

[1] Prosser White R *Lancet* 1901, 2 582, 769

[2] Legge T M Annual Report of Chief Inspector of Factories for 1917, p 21

Dr W A **BRADLEY** had followed the spread of *Strep pyogenes* infections in Addenbrooke's Hospital and had found different types prevalent at different times Thus types 8 and 3 were prevalent in some wards at the beginning of the investigation, but they had then disappeared for some years At other periods he found types 6 and 22 Outbreaks of a single type would last about three months and spread slowly, often just when a general spread seemed imminent that type disappeared spontaneously After a time it became possible to tell how a strain came in type 6, for example, was introduced by a case of cellulitis He found it hard to suppose that dust or bedclothes infections played more than a minor part in spread In a public school which he had investigated spread of infection seemed to be related to the placing of beds in the dormitories, not to exposure to dust in playrooms and corridors

Lieutenant-Commander **JOHN BUNYAN** said that organisms grown from a wound had no significance unless they were causing symptoms If the wound was encouraged to heal from the start contamination by bacteria became less important The use of the Stannard oiled silk envelope made it very difficult for secondary infection to occur The envelope could be applied immediately by anyone and left in position for three weeks The wound could be treated by irrigation with electrolytic hypochlorite solution If the wound was healing well inside the envelope the type of organisms to be found outside became merely academic

Dr E T C **SPOONER** described a study carried out at Hill End Hospital from November, 1940, to April, 1941, inclusive, in a plastic surgery ward Swabs were taken from wounds and throats, and it was found that 65% of wounds were infected with hæmolytic streptococci, and that a quarter of these infections began while the patients were under observation In one epidemic due to a type 13 organism, 3 throats and 15 wounds were infected (one wounded man was seriously ill and 4 Thiersch grafts failed) A type 4 epidemic, starting from 5 burns infected with the same organism admitted together from the same hospital, spread to 18 throats and 4 wounds The type 13 organism had been found by Colonel Colebrook to be resistant to sulphanilamide whereas the type organism was susceptible to the drug All wounds were being treated with sulphanilamide powder This experience illustrated the need for continual investigation which alone could give that fresh insight likely to extend what was known about the control of infection

Mr H W **RODGERS** said that he had been attempting to reduce the smell of the closed plaster method of treatment by enclosing a sheet of gauze soaked in strong antiseptic between the layers of the plaster This, besides preventing the smell from becoming serious for three weeks, retained much of the pus seeping from the wound He asked whether it would also have an effect in preventing cross-infection Professor **MILES** replied that on general principles a layer of strong antiseptic might be expected to reduce the number of bacteria coming through the plaster

Reviews of Books

Warwick and Tunstall's First-aid to the Injured and Sick

(18th ed) Editor **NORMAN HAMMER**, M R C S, late R A M C, county surgeon, St John Ambulance Brigade Bristol John Wright and Sons Pp 336 3*s* 6*d*

THIS is an advanced ambulance handbook Part 1, on anatomy and physiology, is well written, and gives much more information than that usually found in first-aid textbooks Part 2 has been largely rewritten, and includes notes on air-raid casualties, war gases, transport and methods of blanketing a stretcher Busy doctors faced with fallow and inquisitive first-aid classes will welcome it as a reference book Others may argue that first-aid should never be an advanced subject that its greatest value lies in its limitations The great surgeon and the St John Ambulance man are brothers by the roadside, and perhaps there is a growing tendency today to teach too much in the name of first-aid, reports by competent authorities tell of dangers too Should we not be wiser in these days of war to teach the greatest number of people the simplest facts of common sense that save life ?

The book is full of excellent suggestions and explanations, but ancient illustrations, depicting self-conscious gentlemen of bygone days, have become the depressing but inevitable trade mark of first-aid textbooks Clear illustrations are an immense help to the student May we hope in the future for clear line drawings of artistic merit, and more of the type of illustration shown on page 199 ?

Biologic Fundamentals of Radiation Therapy

FRIEDRICH ELLINGER, M D, research fellow, radiotherapy department, Montefiore Hospital, New York City, formerly privatdozent in radiology, University of Berlin. London, H K Lewis and Co Pp 360 30*s*

THIS is a comprehensive survey of the literature of all types of radiation used in medicine—ultraviolet light, X rays and gamma rays The action of radiation on the cell is considered first, followed by an important section in which the action of X rays and gamma rays on the tissues of the human body are described in detail The effect on the skin is regarded as being of special importance because it was the biological indication used in all the earlier methods of estimating dosage, and because the production of irreversible reactions in the skin limits the dose which can be given through any external portal Different organs and tissues are considered and much experimental work is quoted The chapters on the therapeutic uses of radiation are less satisfactory because the task is more difficult In the last twenty years the science and practice of radiology have been changing so quickly that opinions firmly held a few years before may be regarded as out of date even by the author who originally published the conclusions, and the selection for quotation of work based only on reliable experimental evidence is impossible at the present stage It is not in line with modern thought, however, to include Hodgkin's disease as an infectious new growth, while the closely related and sometimes indistinguishable lymphosarcoma is mentioned in a short section on sarcoma in general as if it were a neoplasm of the skin only Dr Ellinger points out that the doses mentioned are merely given for orientation purposes, but they reflect the confusion in practice, including as they do doses in S E D, r in air, r on skin with backscatter, skin doses per field and summated dose, and for radium milligramme hours

Part 2 is concerned with corpuscular radiation, and includes the absorption of emanation and some controversial therapeutic methods, with a short appendix on neutrons Part 3 deals with ultraviolet light—the changes it produces in the skin, its antirachitic effect and its use in the treatment of tuberculosis Among other matter in part 4 is a chapter on diseases caused by light, is interesting, but the possible carcinogenic effect of bright sunlight might have received more attention In the fifth part some general principles of radiation biology and therapy are considered and this provides a convenient summary of opinion on the method of action of radiation, radiosensitivity, the time factor and dosage There is an excellent bibliography and the whole book will be most useful for reference

Essentials for Final Examinations in Medicine

JOHN DE SWIET, M D Lond, M R C P, assistant physician to Staines Emergency Hospital London J and A Churchill Pp 168 7*s* 6*d*

THIS is a small volume of precis articles arranged under 93 headings in alphabetical order They are practically specimen answers to "spotted" questions, largely compiled from standard textbooks and recent monographs The style is succinct and clear, the matter, with occasional exceptions, would be acceptable to *orthodox* examiners, though some might wish for more emphasis on the relation of anginal pain to effort, and some might wonder how it comes about that "the smaller the dose of zinc protamine insulin the sooner it comes into action" But on the whole the student whose own notes are incomplete will find these useful and reliable for last-minute revision

TRAUMATIC DEAFNESS

WHEN man learnt to make noises louder than nature ntended his ears to bear traumatic deafness must have made its appearance and gunfire deafness must have ome in with guns, though the first cases reported, ccording to Goldstein,[1] seem to have been those of Solomon Alberti of Nuremburg in 1591, when guns had been in use for some 200 years The ndustrial revolution, and particularly the development of heavy industries during the present century, has added another form of traumatic deafness Long exposure to the louder industrial noises produces temporary, or sometimes permanent, deafness in certain people—so called boilermaker's deafness Between 1915 and 1930 most aircraft were of the open-cockpit type and the pilot and passengers were exposed to the noise of the engine and air-screw and also the wind-rush In this period otologists in various countries discussed a form of deafness which aviators developed as an occupational disease All agreed that temporary deafness was almost the rule and that permanent deafness was reasonably common The type of deafness was identical with that found in other noisy occupations, and in fact all forms of traumatic deafness where there is no gross demonstrable lesion of the drum, ossicles or bone are of a similar type, varying only in severity Politzer[2] described traumatic deafness as being of the nerve type, and this view is supported by Kerrison[3] The differentiation from other forms of nerve deafness was first made by Bunch[4] in an analysis of a number of audiometric tests In senile deafness there is little loss of auditory acuity for tones up to about 512 double cycles, but thereafter the acuity diminishes almost proportionately to the rise in frequency Toxic deafness follows a somewhat similar, but usually more intense, pattern Bunch found that the hearing in cases of traumatic deafness is fairly normal for frequencies up to 2048, after which there is an abrupt fall in the curve, maximal at 4096 double variations and improving at higher frequencies A similar finding was recorded by Fowler,[5] who also formulated the generalisation that the medium-high frequencies are especially sensitive to insult from trauma or toxins These observations indicate a lesion of the second half of the basal whorl of the cochlea, and confirmation came from an investigation of the microscopic anatomy by Crowe, Guild and Polvogt,[6] who discovered that there was atrophy of the organ of Corti at a level above the last 2 mm of the basal turn This region corresponds fairly exactly to the opening of the oval window and to the promontory on the inner wall of the middle ear In other words, that part of the cochlea nearest the external world and first receiving the auditory impulses suffers most damage

In attempting to avoid deafness due to noise, blocking the external meatus has been advised and used for years For the less intense and prolonged noises the method is reasonably successful Dickson and Ewing[7] have recently investigated various methods of protecting personnel engaged in flying modern aircraft or handling them on the ground The noise with which they were concerned is very loud, lasts for a considerable time and is subject to brief impulsive intensification In addition to protecting against these peculiar noise properties, the method sought had to permit the reception of intelligible speech As might be expected, the solution of so paradoxical a problem was not wholly satisfactory. Two forms of protective appliance were investigated —ear-plugs of various materials, and complete helmets The chief function of the ear-plugs was to reduce air transmission through the middle ear, and of the helmets to insulate the bones of the skull and reduce conduction through the bony capsule Combination was more effective than either method alone but proved unpractical because of the gross interference with the reception of speech With both methods there was less protection against noise in the lower than in the higher frequencies, but it has already been shown that the deafness occurs in the medium-high range where it causes the greatest handicap Both plugs and helmet successfully delayed the onset of aural fatigue but did not abolish it, and this is about as far as it is yet possible to go However, enough has been discovered to indicate that something can be done at least to mitigate one of the many disabilities resulting from war More still might be done if these cases were followed up carefully It would not be difficult to keep men deafened by aircraft noise under observation, to have audiograms done regularly, and to seize any opportunity that fatal accidents offered to secure the temporal bones A few autopsy specimens, backed by a full history and investigation, might teach us much of the pathology of traumatic deafness and show the way to complete prophylaxis

MORE ABOUT PHAGE

THE principle of setting a thief to catch a thief seemed likely to be applicable in therapeutics when first F W Twort and then d'Herelle found twenty-five years ago that cultures of bacteria in the test-tube could mysteriously disappear and when subsequent work showed that many bacteria, pathogenic and non-pathogenic, were the prey of the propagable lytic substance now known as bacteriophage The nature of this substance is still in dispute Most bacteriologists adhere to the view that phage belongs to the virus family, and that there is a multiplicity of phage-viruses each specific for its own bacterial host rather than one omnivorous phage as d'Herelle maintained Others follow Bordet in regarding phage as an autocatalytic enzyme derived from the bacterium itself, while others, like Lwow, believe in a gene origin of phage Whatever its nature, the therapeutist soon found that the promised panacea had once again eluded him, for in both experimental and clinical infections phage proved disappointing The main reason for its failure was its inactivation by any protein or colloid with which it came in contact, although the use of non-specific phage-lysates of weak potency was probably a contributory factor Even in the test-tube a sufficient concentration of phage is required to lyse a bacterial culture Eaton and Bayne-Jones[1] concluded in aeroplane dope or tetrachlorethane In the summer of 1915 other cases occurred and two more deaths were reported Energetic steps were taken to investigate the problem and to prevent cases of poisoning The Medical Research Committee was asked to inquire into the toxicology of T N T and in the meantime LEGGE had warned the factories, on the analogy of experience with the nitro derivatives of benzene, that T N T might be absorbed through the skin or be inhaled as dust or fume, and he recommended that precautions be taken against both these modes of entry. Towards the end of 1915 it became necessary to obtain more information about the prevalence of T N T poisoning and toxic jaundice became notifiable under section 73 of the Factory and Workshop Act, 1901, although T N T also sets up dermatitis, gastric symptoms, cyanosis (methæmoglobinæmia) and aplastic anæmia LEGGE explained that the jaundice of T N T poisoning was chosen because when a statutory notification of an industrial disease has to be made the doctor and the factory occupier usually need a definite symptom or sign to guide them An attempt to notify all the forms of T N T. poisoning would mean that the figures would include nearly every T N T worker seeking medical treatment for any complaint The order for notification came into force on Jan 1, 1916, and 181 cases of toxic jaundice with 52 deaths were notified in that year, whereas in 1917 there were 189 cases with 44 deaths The greatest number of cases were observed towards the end of 1916 and the beginning of 1917, after which the incidence of toxic jaundice and deaths fell rapidly although many more workers were engaged in the manufacture of T N T and in the shell-filling factories Writing in war-time LEGGE could not give the precise numbers of workers exposed to the risk of poisoning but he indicated that there were well over 50,000 so employed In the meantime MOORE,[3] with his colleagues WEBSTER and WYON, had been carrying out in the laboratory and the field a brilliant series of researches which established the fact that T N T made its way into the body more often through the skin than by way of the lung passages or the alimentary tract Early in the inquiry WEBSTER[4] evolved a chemical method of determining the excretion of altered T N T in the urine (a modification of the test by INGHAM[5] was published in our columns last week), and armed with this the investigators were able to test the efficacy of the preventive measures which were put into force They also showed that the skins of different individuals had varying capacities for absorbing T N T and letting it through into the blood-stream, and that workers who developed dermatitis rarely showed constitutional symptoms The colour reaction obtained by Webster's urine test is due not to T N T itself but to a reduction product (2 6 dinitro 4 hydroxylamino-toluene), on excretion in the urine this is conjugated with glycuronic acid, which shares with the sulphonic esters the task of removing from the body in innocuous form a large number of poisonous substances which are either formed autogenously in the body or are introduced from without Herbivorous animals show a greater tolerance than carnivora for T N T and man with his mixed diet stands in an intermediate position Some diets yield more glycuronates or glycuronic esters than others and it seemed i ant to provide for all workers on toxic nitro comp a diet with a high yield of these substances—for example, fresh vegetables and fruit Some resemblance was noted between certain manifestations of T N T. poisoning, such as purpura hæmorrhagica, and those of scurvy It may be noted that in war time supplies of fresh fruit are restricted

---

[1] Eaton, M D and Bayne Jones, S *J Amer med Ass* 1934, 103, 1769, 1847 1934

It would be interesting to know how many case of T N T poisoning there have been during the present war but no figures were given in the report of the Chief Inspector of Factories for 1940[6] Last week we published a description by R M EVANS[7] of seven cases of toxic jaundice due to T N T in a shell filling factory Two of the cases ended fatally and in one of these the patient, who died from acute liver atrophy had been in contact with explosives for only 3 weeks before the onset of the illness The second death was from aplastic, anæmia which came on 9 weeks after an attack of toxic jaundice had abated HILTON and SWANSTON[8] in an article on the general aspects of poisoning by tetryl and trinitrotoluene mentioned that they have seen 3 (presumably recent) fatal cases of aplastic anæmia in workers exposed to T N T But we do not know whether the position as regards T N T poisoning is better or worse than it was during the last war Many are asking, as EDWARD VII asked about tuberculosis—"If preventable, why not prevented?" But the principles of prevention of poisoning by T N T are well known and there can be little doubt that as far as is humanly possible they are being applied In T N T factories all workers are under close medical supervision and the engineers cooperate to control the dust and fume But as BRIDGE[9] points out there is still no explanation why some people after a short period of exposure are poisoned by T N T while others working under the same conditions escape ROBERTS,[10] in urging the need for selection of workers, says that those who are susceptible to T N T may not be protected by even the most satisfactory working conditions and most careful supervision He suggests that no one under the age of 19 and no woman weighing less than 105 lb should be allowed to come in contact with T N T, and that anyone with sweaty hands, a history of jaundice or the yellow sclerotics often seen in constipated people should be rejected He also urges attention to the workers' habits of personal cleanliness—whether they sleep in underclothing that they wear at work, whether they bite their nails, or have long tapering ones MOORE made some suggestions about the part played in determining susceptibility by both diet and permeability of the skin, which can be tested by rubbing in a measured quantity of T N T and assessing by Webster's test the amount absorbed and excreted in the urine But, until a really reliable method of pre-employment selection is found whereby susceptible individuals can be kept away from T N T, cases of poisoning are to be expected in small numbers even if all other methods of prevention are rigorously applied Meanwhile workers must not be sacrificed to the exigencies of output by being kept in the workrooms longer than is reasonable

TOWN ⇄ COUNTRY

The evacuation of London school children is now two years old, and in the balance-sheet presented to the education committee of the London County Council on Nov 5 the chairman was able to show a reasonable profit and loss account What the children have missed in the way of formal education they have gained in mental and physical vigour and a new breadth of outlook The constant ebb and flow of children and teachers necessitates the frequent reorganisation of classes, and the scarcity of new entrants makes it difficult to maintain separate departments for juniors, seniors and infants But if classes have a wider range, they are smaller than in London and there is more scope for individual study At school the children may find their quarters cramped and the sanitary arrangements inadequate according to London standards, but good food, early bedtime and fresh air have improved their health and the town children have a better attendance record than the local children and show more resistance to epidemics If there is a shortage of school books and equipment, nature study and practical geography are attractive new lessons, if the gym, playground and swimming baths are small or non existent, and if equipment for domestic science, art and crafts is lacking, the children have found new ploys such as milking, bee keeping, poultry-keeping and, above all, gardening To many it was news that peas, beans and cabbages have a history that goes beyond the greengrocer in Deptford High Street, but now the boy from Bermondsey brags about his "sprarts" and makes his plot an economic as well as a horticultural success

No one can read the report without feeling admiration for the London teachers, who now often look after their young charges in and out of school hours and during the holidays The closer relationship between teachers and children has been one of the gains of evacuation The teachers are often leading rather lonely lives, isolated from books, professional contacts and home ties, yet it is due to their enterprise that the children have sometimes been able to contribute to the life of the community, and school concerts and displays of handiwork have been warmly welcomed by the country dwellers But the country does not seem to have made many lasting converts When the rest of their family remains in town, it is only natural that the children should return when they leave school, and in an inquiry among 1500 "leavers" less than a quarter remained in the reception area, and of these very few were taking up farming or agricultural work

THE STICKINESS OF PLATELETS

It is a classical observation that blood-platelets and white cells collect at the point of injury of a blood-vessel and there form a thrombus, Osler remarked on the way platelets stick to foreign particles But although methods have been described for estimating the adhesiveness of white cells, no-one has tried to measure this property in platelets Payling Wright[1] has devised an ingenious method of following the changes in the stickiness of blood-platelets that are caused by the use of various anticoagulants, and incidentally she has suggested an explanation of the disappearance of platelets in stored blood Specially shaped glass bulbs were used which had carefully ground apertures at either side, these apertures were sealed with coverslips held in place with soft paraffin Blood was collected in an oiled syringe, mixed with dry anticoagulant in a waxed beaker, and then transferred to the glass bulbs which were steadily rotated by a motor For control, some of the blood was put into a bulb coated on the inside with soft paraffin The platelets were counted by a standard method before the blood was put into the bulbs and then at regular intervals afterwards Finally the coverslips were detached, stained by Leishman's method and examined It was found that after 80 minutes the platelet count had fallen to between 60 and 20% of the original count, the final figure depended on the anticoagulant used, but still more on the concentration of the anticoagulant Oxalate, heparin, chlorazol pink, and chlorazol blue were tried With a concentration that would just prevent clotting the platelet count after 80 minutes' rotation fell to 20–25% of the initial count with all these anticoagulants, but when concentrations of eight or more times minimal were used the final count in oxalated blood was about 60% of original and about 45% with the other anticoagulants In the control bulbs there was only a slight fall in the platelet count When the stained coverslips were examined, the missing platelets were found sticking to the glass, and it was noticed that at the higher anticoagulant concentrations the platelets tended to adhere only to the glass and not to each other Payling Wright concludes that anticoagulants reduce the stickiness of platelets, possibly by reducing fibrin formation on their surfaces The disappearance of platelets in stored blood is due to their adherence to the walls of the storage bottles and not to disintegration, for had this happened clotting might well have been expected when the anticoagulant concentration was minimal and the fall of the platelet count large, but no clotting occurred This technique can clearly be extended to pathological problems Are the blood-platelets less sticky in purpuras ? Can "thrombasthenia" be demonstrated ? Will the answers help us to decide between the orthodox school who think that the stickiness of blood-platelets assists the actual plugging of injured blood-vessels and those who hold that they only help to initiate clotting in the shed blood[2] This method might also be used to seek materials, possibly plastics like Perspex, that platelets will not stick to and could be used for the collection of platelet containing blood

TOO MUCH OF A GOOD THING

Nature has been none too bountiful with her supplies of the vitamins, as the widespread incidence of deficiency diseases shows The possibility of overdosage, therefore, hardly arose before the interference of man led to the detection, isolation and finally synthesis of several of their number After the synthesis of calciferol by the irradiation of ergosterol, the too energetic exhibition of this substance to infants and children led to several instances of undue calcification and occasional death[3 4] Hypervitaminosis A has not yet been described in humans, although it can be produced experimentally in rats[5] Overdosage is more readily to be expected with these fat soluble vitamins, which are not easily eliminated by the body, than with the water-soluble factors, excess of which is readily excreted in the urine Nevertheless, a large dose of a water-soluble vitamin might cause for a short time a high concentration in the blood and so possibly lead to untoward symptoms This, for example, is true of nicotinic acid Doses of more than 50 mg by mouth or 10 mg intravenously may produce flushing and irritation of the skin, and occasionally gastrointestinal symptoms[6] These effects are transitory, the concentration of the vitamin in the blood rapidly falls as the excess, which is not metabolised or stored, is excreted by the kidneys Whether large doses of the other water-soluble factors produce undesirable reactions is not certain It has been suggested that intense treatment with vitamin B_1 may give rise to symptoms akin to those of herpes zoster—intense irritation of the skin and a burning pain in peripheral nerve areas[7]

1934 that the field of phage-therapy was limited to surface infections, whether of skin or mucous membrane, such as pyodermias, urinary and intestinal infections, and both in America and on the Continent phage still enjoys a certain popularity in the treatment of such conditions as boils, cystitis and dysentery The work done since 1934 has been critically reviewed by KRUEGER and SCRIBNER,[2] who point out that there may be a variety of reasons other than direct lytic action on the pathogen for the apparently beneficial action of phage in both local and systemic infections For example, intravenous injections of phage-lysates may, in virtue of their content of broken-down protein, stimulate a leucocytosis or produce the condition of protein shock which often helps to overcome a subacute infection Phage-lysate certainly stimulates the formation of specific antibody to the infecting organism, as GREENWOOD, TOPLEY and their co-workers[3] demonstrated in mouse-typhoid Sometimes, as in the case of the staphylococcus, the phage denatures the bacterial protein, but any preformed toxin would still be present More specifically, phage might attack the more susceptible infecting organisms, leaving a less susceptible but also less virulent variant to be overcome by the host's tissue, but GREENWOOD and TOPLEY found when using phage in attempts to control epidemics of mouse-typhoid that a natural variation of this kind hardly ever occurred Applied locally, as in the treatment of boils, the beneficial effect of phage may again be due to a non-specific stimulus of the host's defensive mechanism, for local applications of bacteria-free nutrient broth have been found to be equally effective

When these collateral effects are discounted, bacteriophage is still found to act specifically on certain bacterial infections, provided it can be applied in sufficient concentration The diseases which hold out most promise of success are the local bowel infections—dysentery and cholera—and it is particularly important just now to know what phage can do for these A great deal of work on the prevention and treatment of cholera with phage has been done in India MORISON[4] has treated wells in certain districts of Assam with anticholera phage while other districts served as controls, and his results seem promising In treatment MORISON's fatality-rates in two large series were 22 6 and 21% for treated cases and 55 6 and 70% for controls, with a greatly diminished secondary case-rate in the families of treated cases PASRICHA and his colleagues,[5] in a carefully controlled series of hospital cases, recorded only a slight difference in the fatality of phage-treated and untreated cholera, but among bacteriologically positive patients the fatality in the treated group was only 8 3% compared with 20 6% for the untreated Thus, the evidence is favourable to the continued use of phage both in the prevention and treatment of cholera In dysentery the position is more controversial Enthusiasts like COMPTON[6] recommend phage-therapy without reservation and claim dramatic results From Germany[7] comes a report of the treatment of 32 soldiers suffering from a mild Flexner infection with disappearance of symptoms in 2–4 days 10 c cm of a dysentery polyphage was given in coffee after a preliminary dose of 0 5–1 g of soda bicarbonate to protect the phage against the destructive action of the gastric juice Others have claimed that dysentery phage can be used as a prophylactic in local outbreaks of the infection, and the war in the Middle East should provide an opportunity for testing the value of phage in dysentery under controlled conditions But potent and specific lysates must be used if any success is to be obtained

Phage has been used extensively in America for the treatment of local suppuration, and indeed ALBEE believed that the healing of chronic osteomyelitis by the Winnett Orr technique is largely due to spontaneous or implanted phage-activity Phage seems to have yielded good results in peritonitis and intestinal perforation but there it is likely to be superseded by the local application of sulphonamides In systemic infections it has been applied principally to the treatment of staphylococcal septicæmia In a recent series LONGACRE, ZAYTZEFF-JERN and MELENEY[8] divided their cases into those treated with phage before and after 1936, when a more potent phage was introduced In the first group of 15 cases the fatality was 73 3%, in the second group of 21 cases it was 28 5% They gave frequent and increasing doses intravenously until the patient was getting 50 c cm per day, and claimed that phage of high potency, given early and in adequate dosage, offers a good prognosis in this serious infection KRUEGER and SCRIBNER are doubtful if the benefit reported in septicæmic conditions can be due to a direct lytic action on the organisms in the blood stream or tissues, yet the experimental work of ASHESHOV, WILSON and TOPLEY[9] showed that antityphoid phage injected intravenously could inhibit infection in mice given a lethal dose of the organism intraperitoneally, though it did not cure an established infection Other workers have confirmed these experimental results, which demonstrate that phage injected parenterally is not wholly inactivated by the host's tissues Thus, although phage-therapy is for the time being overshadowed by chemotherapy, it may yet prove a useful weapon

GERMAN VITAL STATISTICS —An official bulletin gives the number of marriages in Germany in 1940 as 715,400 against 944,331 in 1939 The number of live births in 1940 was 1,644,752 and the birth-rate per 1000 inhabitants 20 4 In the territory of the old Reich the birth rate dropped to 20, the balance being made up by Austria, Sudetenland, Memel and Danzig It is estimated that as a result of the war 150,000 fewer children were born in 1940 The number of deaths for 1940 was 36,450 more than in 1939 The death-rate increased by 0 4 per thousand to 15 This increase is attributed to the cold spell in 1940 The most important causes of death were cardiac diseases 19 6%, cancer 16%, cerebral apoplexy 10 2%, pneumonia 9%, tuberculosis 6 8% The increase in deaths from tuberculosis—2000 more than in 1939—is also ascribed to the cold spell Infantile deaths were roughly 7500 more than in 1939 The death rate per 1000 live births was 65 The net increase in population amounted to roughly 600,000 Some figures for the first quarter of the year 1941 have already been cited (*Lancet*, Aug 23, p 235)

comes a damping medium The larger the
of the bell chest piece the better its response
tched sounds This is accomplished at the
f high frequency components By increasing
re of the bell chest piece on the patient s chest
le to increase the natural period of the skin
n and thereby attentuate the lower-pitched
ts Higher-pitched sounds are then accen-
a result of the decreased masking effect Thus
nd second sounds, and a loud systolic murmur
w pitch are damped down, while a high-pitched
murmur will stand out better When the
on the chest piece is reduced, low-pitched
third heart sounds and gallop rhythms may be
ore readily The diaphragm type of chest
pecially useful in detecting faint, high-pitched
ch as the diastolic murmur of aortic incom-
id the ' bronchial " respiratory sounds If

WEAT-GLANDS IN THE DOG

illusion has been shattered though not
for the first time Speed,[18] of Edinburgh,
ken the trouble to fix pieces of dog skin in
make microscopic sections, has found sweat-
them He makes no claim to a special
, he has simply followed the biblical injunction
From his fairly comprehensive summary of
literature it appears that others have done the
d have *not* always been rewarded Nevertheless
nvestigators are quoted who have described the
at various times during the last 75 years They
in their estimates of incidence and distribution and
way the glands communicate with the surface
says that in the hairy parts the glands open into
ons of the hair follicles between the opening of the
s glands and the skin surface They are numer-
he skin of the lips, head, back, thorax, shoulders
hs, but few over the abdomen and groin They
ent on the hairless skin of the muzzle on the
and on the perinæum The sweat-glands of the
the feet are easily seen because of the absence of
follicles, and, unlike the others, are coiled Thus
s the fallacy that the dog pants because he cannot
over the general surface of his body Neverthe-
does *pant*, and no microtome can strip him of this
own singularity Perhaps he keeps a large part
' evaporation reserve ' in the surface of his tongue
pper respiratory tract, in which case his equipment
king use of the latent heat of evaporation of water seems to be more varied than that of man No doubt other investigators will pursue the matter further to see whether this advantage is shared by breeds other than the half dozen tested by Speed It would be interesting to know how effective the sweating is The fact that no visible moisture appears argues efficient vaporisation The probability that a relatively stagnant atmosphere saturated with water vapour is enmeshed in the hairs suggests the reverse

REPAIR OF THE PERINÆUM UNDER LOCAL ANÆSTHESIA

ATTENTION was drawn last week (p 569) to the use of local anæsthesia in normal pelvic delivery, and in minor obstetric procedures such as episiotomy and the application of low forceps Local anæsthesia should also have a place in domiciliary midwifery in the suture of perineal lacerations Williams[1] points out, very rightly that all perineal tears however trifling, should be sutured immediately after delivery In the patient s home this means that a second doctor has to be summoned to give an anæsthetic, otherwise the tear is neglected or inadequately united, either without anæsthesia or under anæsthesia administered by the accoucheur himself—a procedure which leads to carelessness in asepsis and lack of proper supervision of the anæsthetic Local anæsthesia overcomes these difficulties and the technique is simple No special instruments are necessary and the only requisite is some form of support to control the patient in the lithotomy position The left lateral position is unsuitable in that it tends to approximate the torn edges of the wound and so mask the extent and complexity of the area of operation To ensure an optimum position, the patient's coöperation must be obtained and the nervous patient is unsuitable for this type of anæsthesia An ordinary 10 c cm record syringe is used with fine hypodermic and long serum needles The solution Williams recommends is 1% procaine without the addition of adrenaline The skin edges of the tear deeper structures and muscles are infiltrated generously, but not so as to balloon them unnecessarily No 2 non chromicised or chromicised catgut and a sharp curved cutting needle are recommended a needle holder is a useful accessory, but not essential The area of operation is properly isolated with towels and gently swabbed over with an antiseptic solution such as Dettol The tear is carefully explored to ascertain its extent, but no matter how severe it may be it will be suitable for suture under local anæsthesia It must not be forgotten that a small skin tear may indicate serious deep vaginal lacerations running high up towards the vaginal vault hence the importance of a preliminary survey before starting suturing For inspection a portable headlamp allows the operator to move about freely and does away with the need for an assistant to illuminate the site of operation When the repair is complete a finger is inserted into the rectum to assess the power of the anal sphincter and the anatomy of the perineal body; this will also exclude the unlikely possibility of a suture having transfixed the mucous membrane of the rectum Should this last disaster be found the whole wound must be taken down and resutured, as such a stitch may actually lead to infection and might predispose to a subsequent fistula Neal Smith[2] has reported on the successful suture of 17 unselected cases of perineal laceration, ranging from a small first degree to a serious perineal tear Some were hospital and some district cases and all healed by first intention without any complication The technique used was exactly similar to that of Williams except that 2% procaine was used instead of 1% It is probably always an advantage to use more of a weak solution in local infiltration anæsthesia than less of a strong solution, the ideal

In all these instances excessive intake produces—or is said to produce—changes which are related to the known action of the factor concerned as indicated by the effects seen in deficiency This was first shown with hypervitaminosis D, which gave rise to an increase in the blood level of phosphate and calcium with consequent calcification [4] Excess of nicotinic acid affects the skin and occasionally the gastrointestinal tract, and excess of vitamin B_1 is reported to affect the nerves A novel aspect of hypervitaminosis, however, has recently been studied by Loewenthal of Basle [8] He suggests that large amounts of ascorbic acid, which are excreted by the kidney, might produce changes in the urine conducive the formation of urinary calculi Loewenthal or 2 g of the vitamin daily for five weeks and t several types of investigation—some rather on the urine before and during this period t of the vitamin was to produce an increase in atable acidity of the urine, an increase in the ty and a change in the gold-sol reaction (a test y applied to the C S F). He does not pro the ble to explain the exact nature of these last two nges but interprets them simply as indicating an teration in the "protective colloids" of the urine This, together with the increased acidity, are assumed to imply a greater tendency to the formation of urinary calculi These tentative conclusions will require a great deal of confirmation and elaboration But even if true, they will certainly not deter us from the appropriate and adequate treatment of suspected deficiency of vitamin C The daily requirements of the vitamin are probably about 50 mg and even a case of severe scurvy will be cured by the administration of 1 g daily for a week or two Doses such as those taken by Loewenthal are thus rarely if ever required Moreover, the fact that unnecessarily large overdoses of vitamin D produce toxic symptoms has not interfered with the cure or prevention of rickets by the intelligent use of this substance

The danger of hypervitaminosis in ordinary conditions of therapy or prophylaxis is often exaggerated, but its existence may at least serve the useful purpose of directing attention to the quantitative aspect of vitamin dosage There is a tendency to order a convenient preparation without thinking of the amount of the vitamin really desired The possibility of overdosage, and incidentally a great deal of waste of precious nutritional material, will be avoided when vitamins are prescribed in units or milligrammes or in human "daily shares" and not as so many capsules or tablets

MANIFESTATIONS OF ENDEMIC FLUOROSIS

SURVEYS in America [9] and in England [10] have shown that in children the mottled enamel of mild endemic fluorosis is associated with a greater than average resistance to dental caries, and that the toxic action of fluorine tends to affect those whose general nutrition is poor In other parts of the body fluorine may exert an indirect action Young and his colleagues [11] pointed out that in the ætiology of endemic goitre the absolute iodine content of the water and soil is not the only factor and that something else determines the availability of the iodine to meet human and animal needs In at least one area of this country, among people living under conditions of low iodine intake Wilson [10] has established relationship between the distribution of goitre, of luorine in rock and of mottled enamel In the locomotor ystem fluorosis especially attacks tissues rich in calcium Roholm [12] described the pathological calcification of endons, ligaments and fasciæ, and the formation of steophytes among cryolite workers absorbing large amounts of fluorine In endemic human fluo changes were first detected by Shortt and others [13] communities in South India, and subsequently and his colleagues,[14] by comparative dietary among these same people, showed that the incid bone deformity bore a definite relation to the and nutritional state of the communities con indicating again that the toxicity of fluorine is made evident by a "poor" diet Recently Ockerse [15] in Africa has described bone changes among villagers in Pretoria district using borehole water containing 11 parts per million of fluorine Clinical sym include stiffness of the spine in the lumbar, thoracic cervical regions, and pain and stiffness around the of the arms and legs and lumbar regions The grams of an advanced case show ossification with ing density of bone and calcification of the lumbar thoracic vertebræ and attachments, osteophytic growths and periosteal deposits are also present along radius and ulna and around the elbow-joint and of the ribs The clinical picture is similar to that of most severe cases in South India Fluorine, then, has the claim to be one of the trace elements necessary for infection but its intake must be carefully limited tion, of ed with adequate iodine and the other balanc LONG ng ossification Unfortunately we have a long influence their c before we can decide what the optimum way to go after 1, and can ensure that everyone gets it of fluorine is In ti

STETHOSCOPES OLD AND NEW

3% , in 1816 when Laennec took a quire of

SINCE that day They to form a tube and applied it to the paper, rolled it up ly unoung woman, the art of auscultation chest of a corpulent y and cla fine degree. Although has been developed to and in ms to have been practised by diate " auscultation sees seriou medical men were slow Hippocrates and Harvey tful if of the heart sounds Indeed appreciate the significance in be of Venice, rejected Harvey's Parisanus (1663), a physicians in " Nor we, poor deafs, nor observations with the words ental on " The great Corvisart, any other doctor in Venice c ved tha er, referring to the heart he who can hear them in Lond d inhib had an opportunity, I nearly two hundred years lat rganism uestionably rare observa sounds wrote "I have never n estat strokes by applying my repeat it, of ascertaining the unq ned thes Both statements tions, I have barely heard these Mackenzie's words ear close to the patient's chest " that p n "Indeed I am their obtuseness, recall Sir James M tivated ay examination another aspect of cardiac examinati therapy ht on any cardi doubtful," he wrote in 1920, "if an X-r mothera the perforat the heart has ever thrown the slightest lig while Piorry condition " From the roll of paper to eleney, F e and che wooden cylinder was Laennec's next step, W C monau modifications and his addition of ear piec Lamb piece in 1828 resulted in what is essentially the stethoscope of recent times Williams probably desig the first binaural model about 1843 while Camm replaced the lead tubes by flexible ones in 1855 Th briefly, was evolved the modern binaural stethoscope

The chest piece in all these models was funnel trumpet shaped In the phonendoscope, invented Bianchi in 1894, a diaphragm chest piece with a rig membrane was first used The combined bell a diaphragm chest piece of the latest models seem sat factorily to cover the acoustic ranges necessary clinical examination of the heart and lungs In a rec study of the laws governing auscultation Rappaport Sprague [16] of Boston point out that the bell chest p when applied to the patient's chest functions in rea as a diaphragm chest piece The skin enclosed by lip of the bell acts as a diaphragm, while the subcutan

[16] Rappaport, M B and Sprague, H B

ssue becomes a damping medium The larger the iameter of the bell chest piece the better its response) low-pitched sounds This is accomplished at the xpense of high frequency components By increasing ie pressure of the bell chest piece on the patient s chest ne is able to increase the natural period of the skin iaphragm and thereby attentuate the lower-pitched omponents Higher-pitched sounds are then accen-uated as a result of the decreased masking effect Thus oud first and second sounds, and a loud systolic murmur f fairly low pitch are damped down, while a high-pitched iastolic murmur will stand out better When the ressure on the chest piece is reduced, low-pitched murmurs, third heart sounds and gallop rhythms may be licited more readily The diaphragm type of chest iece is especially useful in detecting faint, high-pitched ounds, such as the diastolic murmur of aortic incom-etence and the ' bronchial " respiratory sounds If ie diaphragm is too thick, however, there is a general eduction of sound intensity Rappaport and Sprague ound that the optimum diameter of the bell chest piece 1 in and that of a bakelite diaphragm 1½ in , the ickness of the latter should be about 0 015 in The maller the diameter of the bell the higher the pitch of ie sounds They think that the bell should not be con-dered primarily as an accumulator but rather as a icrophone or telephone receiver Finally, as many udents may have suspected when they began clinical ork, they find the length and calibre of the rubber ibing important They show that the pressure variaons at the ear, produced by the motion of the skin or akelite diaphragm, are inversely proportional to the ternal volume of the stethoscope It follows, there-re, that the tubing should be as short as possible and ie calibre as small as possible The wall of the tubing iould be sufficiently rigid to prevent any wall motion, r that would reduce the effective pressure variations ansmitted to the observer's ear Here they differ om Johnston and Kline,[17] but the latter reached their nclusions as a result of experiments on the human aver with a mechanical ear

SWEAT-GLANDS IN THE DOG

ANOTHER illusion has been shattered, though not parently for the first time Speed,[18] of Edinburgh, o has taken the trouble to fix pieces of dog skin in mol and make microscopic sections, has found sweat-nds in them He makes no claim to a special hnique, he has simply followed the biblical injunction seek From his fairly comprehensive summary of rious literature it appears that others have done the ie and have not always been rewarded Nevertheless, t investigators are quoted who have described the ds at various times during the last 75 years They their estimates of incidence and distribution and ay the glands communicate with the surface ys that in the hairy parts the glands open into ns of the hair follicles between the opening of the is glands and the skin surface They are numer-he skin of the lips, head, back, thorax, shoulders hs, but few over the abdomen and groin They nt on the hairless skin of the muzzle, on the and on the perinæum The sweat-glands of the the feet are easily seen because of the absence of follicles, and, unlike the others, are coiled Thus the fallacy that the dog pants because he cannot ver the general surface of his body Neverthe-does pant, and no microtome can strip him of this own singularity Perhaps he keeps a large part evaporation reserve " in the surface of his tongue per respiratory tract, in which case his equipment king use of the latent heat of evaporation of water seems to be more varied than that of man No doubt other investigators will pursue the matter further to see whether this advantage is shared by breeds other than the half dozen tested by Speed It would be interesting to know how effective the sweating is The fact that no visible moisture appears argues efficient vaporisation The probability that a relatively stagnant atmosphere saturated with water vapour is enmeshed in the hairs suggests the reverse

REPAIR OF THE PERINÆUM UNDER LOCAL ANÆSTHESIA

ATTENTION was drawn last week (p 569) to the use of local anæsthesia in normal pelvic delivery, and in minor obstetric procedures such as episiotomy and the application of low forceps Local anæsthesia should also have a place in domiciliary midwifery in the suture of perinæal lacerations Williams[1] points out, very rightly that all perinæal tears, however trifling, should be sutured immediately after delivery In the patient s home this means that a second doctor has to be summoned to give an anæsthetic , otherwise the tear is neglected or inadequately united, either without anæsthesia or under anæsthesia administered by the accoucheur himself—a procedure which leads to carelessness in asepsis and lack of proper supervision of the anæsthetic Local anæsthesia overcomes these difficulties and the technique is simple No special instruments are necessary and the only requisite is some form of support to control the patient in the lithotomy position The left lateral position is unsuitable in that it tends to approximate the torn edges of the wound and so mask the extent and complexity of the area of operation To ensure an optimum position, the patient's coöperation must be obtained and the nervous patient is unsuitable for this type of anæsthesia An ordinary 10 c cm record syringe is used with fine hypodermic and long serum needles The solution Williams recommends is 1% procaine without the addition of adrenaline The skin edges of the tear deeper structures and muscles are infiltrated generously, but not so as to balloon them unnecessarily No 2 non-chromicised or chromicised catgut and a sharp curved cutting needle are recommended a needle holder is a useful accessory, but not essential The area of operation is properly isolated with towels and gently swabbed over with an antiseptic solution such as Dettol The tear is carefully explored to ascertain its extent, but no matter how severe it may be it will be suitable for suture under local anæsthesia It must not be forgotten that a small skin tear may indicate serious deep vaginal lacerations running high up towards the vaginal vault hence the importance of a preliminary survey before starting suturing For inspection a portable headlamp allows the operator to move about freely and does away with the need for an assistant to illuminate the site of operation When the repair is complete a finger is inserted into the rectum to assess the power of the anal sphincter and the anatomy of the perinæal body , this will also exclude the unlikely possibility of a suture having transfixed the mucous membrane of the rectum Should this last disaster be found the whole wound must be taken down and resutured, as such a stitch may actually lead to infection and might predispose to a subsequent fistula Neal Smith[2] has reported on the successful suture of 17 unselected cases of perinæal laceration, ranging from a small first-degree to a serious perinæal tear Some were hospital and some district cases and all healed by first intention without any complication The technique used was exactly similar to that of Williams, except that 2% procaine was used instead of 1% It is probably always an advantage to use more of a weak solution in local infiltration anæsthesia than less of a strong solution, the ideal

being ½ or 1% procaine Smith like Williams urges the importance of early operation and notes that expedition enhances the efficacy of the anæsthesia The advantages of local anæsthesia for suture of perinæal tears have long been recognised by a few obstetricians, but for some reasons any operation performed under a local or regional anæsthetic tends to be unpopular in this country both in the minds of the lay and the pro- [illegible] concerned This is an unfortunate attitude [illegible]ould if possible be overcome Inhalation [illegible] in the mother at or after delivery is always [illegible] with some small risk and this especially in [illegible] [illegible]ated by cardiac, pulmonary or other [illegible]nt diseases, notably toxæmia In these cases [illegible] ch to be recommended that the small extra [illegible] of using a local anæsthesia be cheerfully under [illegible] by the operator, who after all is more con- [illegible]ed with the patient's safety than his own time [illegible]d convenience

SIR ARTHUR HILL, F R S

THE tragic death from a riding accident on Nov 3 of Sir Arthur Hill has removed at the age of 66 years one who was still full of vigour and the zest of life He had been director of the Royal Botanic Gardens at Kew for the past nineteen years where he had succeeded Sir David Prain He had a keen artistic appreciation of the beauties of the gardens which he did much to preserve and enhance During his directorship the extensive addition to the herbarium was erected and the north gallery was restored to its original condition Hill's scientific interests centred chiefly in plant morphology and he took an especial interest in modes of germination and specialised types of seedling structure His contributions to systematic botany included publications of the taxonomy of various genera of which the extensive and medicinally important genus strychnos was one He also edited the supplements to the "Index Kewensis," the *Kew Bulletin*, the *Botanical Magazine* and the "Icones Plantarum" Hill had travelled widely both in connexion with his work and for pleasure and he was a genial and sympathetic companion He was endued with a strong sense of esprit de corps and cherished a deep affection for Marlborough and King's College, Cambridge, where he was educated, while he regularly attended meetings of such bodies as the Royal Society Dining Club of which he was a member He will be remembered by many for his kindly acts—he was of those who delighted to do good by stealth

DARK LANTERN ON RHEUMATISM

THE typical picture of rheumatic fever is sufficiently distinct from that of rheumatoid arthritis for there to be little confusion, but every clinician can remember cases where only the passage of time and the development of the characteristic sequelæ enabled him to make a certain diagnosis In the age groups where they overlap the two diseases come to resemble each other more closely, the disease process, too, is of similar type, and thus the nature of the relationship between the two has always excited speculation and conjecture There are three main theories first the characteristically English view that the diseases are ætiologically distinct and that the occasional occurrence of destructive joint changes and heart damage in the same patient is merely coincidental, secondly, as authorities in New York[1] maintain, that the two diseases are ætiologically related and may be manifestations of the same agent in differently reacting types, thirdly, a German view, that there are two types of rheumatoid arthritis one primary and the other secondary to rheumatic fever A recent study from the Mayo Clinic might be expected to throw new light on this problem Autopsies were made on 25 cases of infectious arthritis whose clinical records had been adequately reviewed by a member of the arthritis unit under the able leadership of Dr Phil Hench[2] The disease had been present for an average of 7 years, the periods ranging from 3½ months to 30 years The new light has, however, as so often happens, merely shown up several dark corners Of these 25 hearts, 14 (56%) showed lesions indistinguishable from those of rheumatic fever, a result on which Hench wisely refuses to comment except in a non-committal way He believes that these cases represent the presence of two coincidental diseases, but it is a curious distribution since only about 5% of routine post-mortem studies at that centre show evidence of rheumatic fever As Hench says, additional observations, both clinical and pathological, must be made on many other cases before final appraisal can be attempted Too often the problems of chronic disease are shelved, like the sufferers themselves, as "lacking clinical interest

INSULIN IN THE TREATMENT OF G P I

A M San Martin describes what he claims to be a new treatment for general paralysis of the insane by means of insulin in addition to antisyphilitics[3] A woman was referred to him in whom antisyphilitic treatment and malaria had failed to bring about any improvement It was decided to try pyretic treatment by means of vaccine, but first, because the patient was in wretched general condition, to give her a high carbohydrate diet and insulin to improve her nutrition After she had been treated in this way for a few days it was observed that not only her physical but her mental state also was improved The treatment was continued and in addition acetarsol was given, in three months' time the patient was able to leave hospital apparently cured Encouraged by this unexpected success, San Martin has tried a similar method in 9 mo[illegible] cases, combining insulin with bismuth or an arsphenamine preparation All were patients in whom malarial therapy had failed In 7 there was striking improvement, 4 being clinically cured, the remaining 2 patients di[illegible] In the first case small doses of insulin were given with care to avoid hypoglycæmia, in the remaining 9 hypoglycæmic doses were given, as for schizophrenia, daily for about 10 days Antisyphilitics were then begun, and the insulin continued except on the days when the patient received an injection of bismuth or arsphenamine It is not stated how long treatment went on Other workers have been using leptazol convulsions or electric shock therapy in G P I[4] In these convulsive therapy was adopted because mental improvement had not resulted from the usual forms of antisyphilitic treatment A distinction must therefore be made between treatment aimed at [illegible] syphilitic infection (and thus preventing furt[illegible] of the disease) and treatment aimed at amelior[illegible] symptoms which persist after the infection has [illegible] eliminated It has long been recognised that sc[illegible]phrenic and other psychotic syndromes sometimes c[illegible] in the course of G P I Some of these may be [illegible] associated psychoses, others have probably b[illegible] produced by the syphilitic lesions themselves The mental improvement obtained in some schizophrenic patients by prefrontal leucotomy suggests that the frontal lobes may play an important part in the symptomatology of schizophrenia Since the lesions produced by neurosyphilis often affect the frontal lobes, it is possible that schizophrenic changes may be induced by these lesions Thus, once the syphilitic infection has been arrested, forms of therapy which have been successful in schizophrenia might be expected to succeed in t[illegible] organically produced schizophrenics But it must [illegible] therefore be assumed that any such new forms of tr[illegible]ment can be a substitute for antisyphilitic remedies

THOUGHTS ON A STATE MEDICAL SERVICE

A G G THOMPSON, MD CAMB, DPH
MEDICAL OFFICER OF HEALTH FOR LAMBETH

MEDICAL planning for the postwar era cannot avoid grave mistakes if the broad conditions of life likely to obtain then are not faced at the outset Two main assumptions are made here which while sweeping in character may not in the time to come be so far fetched as they now appear

First, it can be safely assumed that the more even distribution of the national wealth which is rapidly taking place will after the war eliminate the richest classes in the community To have a net income to spend of £10,000 a year under the present taxation means the possession of a gross income approaching the quarter of a million For a long time to come taxation is not likely to be reduced and to maintain the purchasing value of the saving certificates and war bonds now accumulating will need hard work and hard living for all There will be too little money available for much to reach *voluntary organisations, and the income from charitable* sources which has in the past supported the great voluntary hospitals may be reduced to vanishing point There will also be much less money for the non-panel general practitioners and still less for the consultant These will no doubt remember the lean years from 1930

Next, there seems every chance that the income of the wage-earner will depend not only on the trade-union or other rate of pay applicable to his job but also on some system of family allowances At present only the wage-earner is entitled to the benefits of national health insurance but the net is ever being cast wider and the logical outcome is for the entire family of the wage-earner to be covered by insurance If the head of the family receives allowances from the state it is no more than common sense that the state should make sure that the family gets the benefit, and how better than by compulsory health insurance ?

With these two assumptions in mind the outlook of the medical service serving the postwar community will have to be far different from what it was in pre-war days Willy nilly we must expect the voluntary hospital as well as other voluntary health organisations to disappear or at any rate to undergo a revolutionary change from their present position, and must also expect the bulk of the patients who now attend the voluntary hospital or call in the general practitioner to be covered by compulsory health insurance The future is likely therefore to hold re a state medical service which will embrace a great rity of the community if not almost the whole of it

A REAL FAMILY DOCTOR

aring in mind—what is sometimes overlooked—that edical service is for the benefit of the citizen and not e benefit of the medical profession, is it too optimis- think of the future insurance practitioner being in ge of say not more than 1000 families instead of not than 3000 individuals ? Instead of the wage-earner to his "insurance doctor," his wife calling in some medical man, and his children seeing a welfare- doctor, the school doctor or a doctor at the local itary hospital, the entire family as one unit may well nder the care of one medical man. It would ad- edly be a big job for that man, but behind him in this ined state service there would be consultants from tate hospitals with all ancillary services The state ital for the district would be surrounded by the ite special institutions for infectious disease, tuber- is, maternity and mental cases, and among them d be the "aftercare" and convalescent home, where iod of real convalescence free from all fear of want he dependent family would put the wage-earner y on his feet before he was discharged to face again truggle of life

is "family doctor" would be a real one, not one in only, and he would have to assist him an almoner, lth visitor and a public-assistance officer, working eam to decide the help needed by all or any members amily to regain and maintain health A consulting-room for each family doctor would be provided in the local health centre, where special clinics would be installed such as dentist, oculist, chiropodist, antenatal tuberculosis and so on The qualifying curriculum of the medical student would need drastic revision, with far greater training in the maintenance of health and a corresponding reduction in the vast amount of scientific and clinical information which he is now asked to memorise largely for examination purposes There must of course be compulsory postgraduate training for all, with facilities for research work and training in particular subjects for the future consultants and specialists

ORGANISATION

The state medical service must be decentralised to the highest possible degree, to ensure that its life is not crushed out by the administration. One can picture a ministry of health of moderate dimensions to implement the policy of the state and exercise a general but not a detailed control over a number of regions These regions in turn would supervise the individual districts and coordinate the activities of each with others within the region Some of the special hospitals, for example, might well serve more than one district Holiday camps and convalescent or aftercare homes also seem to fit into the province of the regional staff The districts should be as far as possible autonomous within their broad boundaries Their size must be governed by considerations of geography as well as population but they would be of an extent compatible with efficiency and economy, each including not more say than 250 000 people or an area greater than a hundred square miles, but depending more on travel-time than distance The pay and service conditions of the medical staff would be graduated with increments for years of service and higher pay for the more responsible positions, promotion to which would be gained by combined examination and reports of superiors Pensions, allowances and so on might be based on the conditions of medical service in the Forces Russia has evolved a national medical service and no doubt we could learn from her experience and profit from her mistakes

The position of the local authorities in such a national service would require careful consideration, but if districts were of the size suggested the present local authorities would be superseded The maternity and child-welfare and school medical services would disappear together with much of the activity of public assistance, district nursing and voluntary organisations such as the COS, ICAA, CCHF, and many others The outpatient departments of hospitals would be almost entirely emptied, and with the increasing supervision of the family by the "family doctor" and the support given by convalescent homes and aftercare, many chronic cases would be prevented and the number of hospital beds for all but acute cases might in time be greatly reduced In fact the success of the family doctors in a district could be readily gauged from the number of hospital beds which had to be maintained The opportunities for research would be immensely enlarged, and if doctors could be persuaded to keep a careful history of each member of every insured family light would be thrown on the earliest stage of disease of all kinds

* * *

A state medical service such as here outlined would unify many efforts at present overlapping and conflicting but could the many interests concerned be persuaded that it would be for the benefit of the community ?

COST OF LIVING IN GERMANY —According to the official index for the cost of living in Germany (*Dtsch med Wschr* Sept 26, 1941, p 1074) during July the prices of goods in daily demand were 1 5% higher than in June This increase is attributed to seasonal influences The figure for the total cost of living in July was 136 1 (taking the cost in 1913–14 as 100) as against 134 1 for June The figure for food rose from 130 6 in June to 134 2 in July—an increase of 2 8% This was ascribed to the more general use of new potatoes which were of course dearer than the old ones The price of other fresh vegetables also increased The cost of clothing rose from 158 1 in June to 158 7 in July—an increase of 0 4%

In England Now

A Running Commentary by Peripatetic Correspondents

THOSE charged with the duty of bestowing names have a responsibility which they do not always take seriously enough How otherwise are we to account for the extraordinary names that dog defenceless infants through manhood to old age? War tends to add new terrors to these trials of nomenclature when the unprotesting infant is named after a general, a politician, or even a supply dump Recently our hospital has been involved in a series of exercises involving casualty reception, and it appears that even such exercises must have names Who chooses the names is not a question for ordinary mortals, but their range is almost as catholic as the pass-words of other days The psychology of the chooser seems to run in cycles, for after a series of colourless inanimate efforts like axle, truck or station, he will suddenly dart into the very animate—rabbit, hound, ant or bee It is customary to preface messages about these exercises with the label of the event, and we have from time to time been somewhat staggered to receive an exhortation beginning "Exercise Rabbit," or "Exercise Bee" One's first reaction is to a word of command, and it does seem a little strange, even in these days, to encounter an exhortation to "Exercise Rabbit" "Exercise Bee" is worse, for while the exercise of rabbit can make the exercisor look ridiculous the exercise of bee is not without its dangers But it is surprising how quickly one drops into the vernacular and comes to receive a whole sheaf of messages all beginning and ending with "Exercise Bee" without the quiver of an eyelid These messages touch us in two ways They may send to the hospital a number of "casualties" in flesh or on paper, or they may require us to send some of our surgical pillars out into the wilderness to render assistance elsewhere We do not complain about these things, though their novelty has worn off It may be that we are instructed to stand by for the reception of "casualties" from 2 P M one day (or from 14 00 hours, as the official word has it) until 8 P M next day Since these performances nearly always embrace Sundays they necessarily cancel week-end leave for everyone, and all that commonly happens by way of compensation is that we solemnly make "nil" returns at two-hourly intervals to a whole host of functionaries, seen and unseen, known and unknown Usually at some time or other in the course of the performance one batch of "casualties" does arrive on our door-step, sometimes a mere scrap of paper to the effect that it represents x patients transferred from another hospital, sometimes a collection of warriors said to be more broken in body than they appear to be in spirit These visitations usually descend on us in the early hours of the morning, and they inevitably involve the feeding and watering of the convoy attendants, if not of their burdens Sometimes these burdens announce that they have come to stay for an indefinite period ("until transport can be arranged to take them away"), and, as can well be imagined, this latter development is apt to be coldly received, for the fitter a patient the more nuisance is he likely to be

When we are instructed to send surgical personnel and equipment into a far country there is much beating of wings Ultimately two chariots are laden, one bearing the cream of our personnel, the other the miscellaneous collection of equipment that constitutes the stock-in-trade of a mobile surgical unit, and with a triumphant blast they disappear in search of new worlds to conquer Sometimes these expeditions last only for a few hours, sometimes they extend over night I have never been privileged to see any of these field operations at close quarters, but I am credibly informed that they can be very entertaining Sometimes they include a spirited discourse (flippantly referred to as "pep talk") from some military dignitary, the effect of whose oratory may be dimmed by some such untoward and untimely incident as the fainting of a nurse, or the hiccough of a surgeon, both events outwith the pharmacopœia of the performance Occasionally fate sends our wanderers to spend the night in a country house, where they are treated right royally, to return to us with picturesque tal[illegible] only serve to depress their colleagues, who have been condemned throughou to the everyday The activities of the peripateti surgeons, like these of the stay-at-homes, never seem to assume formidable proportions, they solemnly set up shop and stand like tradesmen awaiting customers in market square, but customers are scarce One of crowning penalties of these exercises is that they for the submission of a report on them, and report we do, usually with brevity, occasionally with vigour, but always in our story adhering to the prescribed ritual, beginning as we end, "Exercise Bee Exercise Bee."

* * *

In this country when a public servant fails in foresight, performance or energy we often take away his responsibilities and elevate him socially Poor old Jones who made such a mess of the Ministry of Tics starts a new life of comparative harmlessness as Lord Neuralgia This admirable method seems to reach almost a Chinese pinnacle of civilisation, but curiously enough the lone, disregarded prophets in the wilderness who suddenly are shown to be right, or at any rate less wrong than the popular prophets, are not rewarded and made ministers There is a grudging, insular feeling in the mass of us who have been mistaken or misled which prevents their immediate acclamation, otherwise we might have recently seen Mr Pritt as Lord Chancellor and Prof J B S Haldane in some very high post indeed For years he has been a strong supporter of Russia, has preached the essential soundness of the Soviet system, and is a confirmed Marxist and Leninist His wonderful little Pelican, "Science and Everyday Life," consists of seventy articles he wrote in the *Daily Worker*, and they deal with a glorious variety of subjects in a terse, witty and fearless way—Why bananas have no pips, Do continents move?, Atom smashing, Colliery explosions, Genetics They who have the restraint might read one a day as a tonic Personally I read the lot at a sitting, and am hungry for more What admirable broadcasts they would make, but it is more than doubtful whether the B B C would allow them Yet any one of these little articles would make a most stimulating "go to" talk at 7 55

* * *

Transfusion centres are apt to grow into monsters and as an itinerant progenitor of these war children one at times feels a little concerned Is it all being overdone? Have we not already got enough plasma and serum to see us into the twenty-first century, and will not many decades of war have by that time reduced us to such a simple standard of living that our plasma-proteins will have been reduced totalitarian-wise into a standard amino-acid capable of synthesis in the laboratory? With the continuous call for scrap will our hæmoglobin molecule not think it best, in the national interest, to come off the iron standard and use chlorophyll as ersatz? Perhaps before such drastic changes are demanded the liver may be able to achieve a greater economy of iron, salvage of the erythrocytes being effected by the reticul endothelial cells to the slogan "use this envelope ten times before discarding it"

* * *

Mention of cucumber seeds with their copper-protein enzyme in THE LANCET of Nov 8 (p 5[illegible]1), sugge that I ought to set out my great copper conserving scheme I suppose it is the result of all these anti waste slogans, but I find myself developing an anti waste or salvage mind I am concerned, in the Quaker sense, with Fehling's solution All biochemists unite to tell us that Fehling's solution is unreliable and only Benedict's solution should be employed in the clinical laboratory test for sugar Despite this warning, or perhaps I may now say ukase, the twin bottles for Fehling's test still live side by side in thousands of test rooms I cannot boast that I have visited all these thousands, but random sampling, so to speak, has shown that Fehling is never absent Now my great scheme to conduct a Fehling's collection campaign Let us ta this chance of a biochemical advance by e ourselves universally to use Benedict and Benedict only Let us save copper by collecting all the misused bottles Fehling's (blue) solution A simple process will copper If all the Fehling's (blue) solutions mistakenly displayed in hospitals and consulting-r were collected, we should have enough copper to make whatever is made from copper I am sure it would sa several shiploads (vide M O I film passim) Details of collection can be worked out locally The great thing is to sacrifice Fehling in a twin campaign of biochemical efficiency and copper economy Who was he, anyway ?

* * *

The great day had arrived at last, and the A D M S was due within the next two hours He was to inspect, of course, the main cook-house of the battalion, and that of a small outlying post, after the good lunch we had arranged to give him had taken its accustomed place in the day's routine As messing officer I had dealt with assistant directors of medical services before, and knew just what they liked the spotless roller towel hanging up, the hand wash-basin with the soap laid out conspicuously *and* the nail brush To the cook-house of the small outlying detachment I sent a young subaltern, with instructions to get the place clean , cleanliness, I explained, was the keynote with any A D M S , and it did not matter so much how the food was cooked, what was being cooked, the qualifications of whoever was cooking it, so long as everything connected with the cooking of it was hygienic Nor was it vital to see that the contents of the swill-tubs had the correct swills in them, so long as they were clean outside and had the lids on them I went to my own cook-house for a final look round with a feeling of confidence , everything was completely A D M S -shape—tables clean, rims of the mustard pot covers shining (a point they are very hot on) and the cooks' faces washed Those men who seem to be incapable of keeping themselves clean had been liquidated for the morning by the staff sergeant cook This was going to be a much easier visit ~~to~~ get through than one from one of those expert-on-food generals who may ask awkward questions about the menu, or demand an exhibition in pastry-making from some poor cook When the victim gets all his quantities wrong from nervousness, the general usually suggests kindly that perhaps he has not done any pastry-making but has always cooked the vegetables , and the cook will eagerly clutch the straw and agree, whereas he has really been making beautiful apple tarts for the past year Oh yes, I thought, this would be much easier than that sort of visit

I went into the back-yard to wait , I should be warned when the party arrived by the main road That potato must be moved I bet I can putt it behind the dustbin with my stick in three One—that was a useful shot Two—I do wish these A D M S s would come the normal way and not arrive suddenly by the back entrance "Good-morning, Sir," I exclaim with a hollow laugh "Yes, sir, quite a good putt I was just going to put it in the swill tub " What ? Have all my cooks been on a cook's course ? This isn't fair, you're supposed to look at my beautifully scrubbed tables Look at this drain, sir , is it clean ? It is ! "Well, sir, I am not quite sure if all the cooks have been on courses or not I shall have to refer to my files I beg your pardon, sir ? How do we make a baked rice pudding ? " This is an outrage What about looking at the cook's spotlessly clean hands, the absence of flies in the larder Hi ! you can't pass that meat-store We've spent hours cleaning it and chasing the blue-bottles out . Besides there's the new piece of butter muslin over the bacon, specially arranged for you That's the last straw, passing the mustard pots without picking up one lid to see if it was clean Not one ! And then, to cap all, asking one of the cooks how to make a jam tart He's only there to look clean It's not fair, I say ; this Army's getting too modern

* * *

I travelled back from an aunt's funeral the other day with the family solicitor, a judicious, nutty, glass-of-sherry-on the-sideboard little man We fell naturally to discussing the old lady and the indomitable pessimism which was her characteristic Ninety years old in the first week of September, 1939, she philosophically remarked, "Well, I'm afraid this is the last war I shall see " And so it was The lawyer quoted to me Sam Weller's words to his father—"Well, ve must all come to it, one day or another , there's a Providence in it " And the father's rejoinder—'Of course there is , wot'd become of the undertakers without it, Sammy ? " This led us on to his experiences (copious, it seemed) of morticians He spoke of their tact and their fees The latter, he thought, were stepped up pretty high, but then the relatives felt it would be disrespectful towards the departed to dispute the bill "And they always get paid first," he added feelingly, " before the doctors and long before the lawyers " Then he asked if I'd seen that recent prosecution at Liverpool assizes of the two undertakers' men who filled the coffins with sand In the confusion after an air-raid they had been unable to find the bodies in time , the funerals were overdue, the relatives were waiting and something had to be done It looked an unsocial and unsettling kind of deception, but, instead of being tried for a public mischief, they were just charged with the offence of making a false entry contrary to the burial laws They pleaded guilty and their counsel claimed that they were really public benefactors , they had done a charitable act , they thought the corpses must have been interred in a communal grave and they carried on with the funeral ceremony so as not to disappoint the mourners who had assembled to mourn I asked the man of law how the deception came to be detected He said the bodies were discovered afterwards What happened to them ? Was there another funeral ? He didn't know Continuing in this macabre vein he offered me another bit of gossip floating round the undertakers' world A patient died of some rare disease His widow acceded to a request from the hospital authorities that they should be allowed to make an autopsy of such an interesting case The body, with some of the organs removed and rather roughly sewn up, was eventually deposited at the mortuary Meanwhile a woman in the neighbourhood had given birth to a stillborn child, and, not wanting the fuss of a funeral, asked a member of the mortuary staff if he could do anything about it As another of these " charitable acts," he said he would see what could be done The sequel was a surprise for a most respectable firm of morticians when its representatives came to prepare the corpse of the hospital patient for decent interment They found the fœtus inside his empty abdomen What criminal offence had been committed and what disciplinary action followed I never learnt, for at this moment, rather to my relief, the railway carriage filled up with young men and maidens whose chatter was of livelier things

* * *

It was the memory that fried tench with mushrooms (or at a pinch sliced young puffballs) is no mean dish that made Uncle take the boy to a pond which he had not fished for thirty-five years Everything seemed just the same as of old—the smell of the water mint, the reflecting and expectant stillness of the water, even the same old clumps of *Potamogeton natans* How proud Uncle had been when he learnt that name from an elder brother forty years ago The white quill float pointed like an uplifted finger, commanding silence , on the other side of the pond the boy's red and green cork one stood perkily, almost aggressively, upright, the moorhen's lovely yodel came from the rushes at the shallow end, everything seemed exactly the same " Anything doing ? " asked Uncle after a while, lowering his voice for the tranquil carrying water. " I thought I had a nibble just now," said the boy, louder Probably a lie, a lie in the best tradition, full of hope and optimism How like that other boy, even the voice " I've got one, hurrah ! By Crumps, it's a wizard Come and look, Uncle ! " " All right, all right, you needn't make all that noise about it You'll frighten the others " Uncle didn't really mind a hoot about the noise, but he was repressing emotion and was therefore a bit irritable, for that other boy has been dead twenty-four years now, waiting in some Mesopotamian sand for the tide of battle to flood again " Qui procul hinc " Uncle admires the fat pounder, lying in the grass, the fine mosaic of his tiny scales, the gold-green sheen, the ruby eye turned down as though to watch the pouting mouth Uncle remembers there was a French master who used to make the same sort of lip movements when pronouncing " ou," and they called him The Tench, which degenerated unjustly into Stinker Uncle relates this trivial incident to the boy who receives it politely as some Chaucerian, or at any rate Edwardian, coarseness Uncle was about to show him how to distinguish the sex by the pelvic fins , better not He tiptoes back to his rod resting on the rushes Thirty-five years ! Tench will probably be the same in thirty-five thousand, gobble up brandling, hook, and all, then look surprised when they gasp on the bank Poor fish Few come back to teach them, few come back But what of us ? What was the boy talking about coming along here ? Hurricanes and Tomahawks, canon or machine guns What was that other boy always reading ? "Famous Battles," "The Green Curve" We are all poor fishes The white quill bobs twice and glides under the water

Letters to the Editor

THE DERELICT SWAB

SIR,—I have read with great interest the annotation on surgery and the common law in THE LANCET of June 7 (p 729) You very much doubt whether the courts of common law will agree with the surgeon's view expressed by Mr Zachary Cope, that, if he receives an assurance from the theatre sister that all the swabs and instruments have been accounted for, the surgeon may sew up the abdomen and be relieved of responsibility if one remains inside I agree with your view that the precautions the surgeon must take to ensure that the swabs are all removed must remain a question of fact in each particular case The theatre sister's assurance is not a sufficient protection even when supported by that of another member of the theatre team

May I relate an illuminating experience ? Many years ago, in the course of an emergency operation late at night for appendicitis in a child, I inserted a protective swab into the abdomen The appendix was removed and the incision closed While driving home in my motor-car the thought suddenly struck me that I had left the swab in the abdomen I returned to the hospital and questioned the theatre sister, who assured me that the swab had been removed I then turned to my house-surgeon, who gave me the same assurance I replied that I was not satisfied and asked the theatre sister to count the swabs before me She did so and one was missing I had the patient returned to the operating theatre and removed the swab

This experience led me to adopt the view that it is the surgeon's duty to accept the responsibility for a derelict swab If he makes an invariable practice of never putting a "loose" swab into the abdomen, he will never leave one there

Adelaide H S NEWLAND

ENURESIS

SIR,—Dr Raymond Greene wonders why I should think it relevant to mention cases of exanthemata occurring after the onset of enuresis The answer is that enuresis often takes a turn for the worse after one of these infections, this was so in a large proportion of my cases The difference between cases showing much dilatation of the upper urinary tract and cases showing little was that the greater the dilatation the more constant the evidence of infection in the urine So well does this rule apply that in the lesser degrees of dilatation, so commonly seen among enuresis cases, it is unusual to find evidence of infection in the urine at all, but where infection does exist it is relatively easy to get rid of it In cases where there is much dilatation, however, it may be impossible to achieve sterile urine, modern urinary antiseptics often reduced the degree of infection, but failed to clear it up completely The difficulty in attaining this end usually seemed to have a direct relationship to the amount of dilatation present The involvement of the urethra in the inflammatory process in all the cases of vulvitis was a personal observation Usually it could be detected by merely inspecting the external urinary meatus I duly acknowledge the correction concerning the sites at which the ducts of the glands of Bartholin open

My studies on the calibre of children's urethras were always made under general anæsthesia at the termination of an endoscopy, on patients whose urinary tracts required such investigation It would be difficult to find an objection to such a procedure on psychological grounds The question whether there might be any relationship between benefit from treatment and a threat of a further instrumentation can be answered finally now and in the negative Since the treatments were carried out under a general anæsthetic the patients had no knowledge of what was done or of what might be done on a future occasion

I can assure Dr Arnold Heymann that in my experience spina bifida occulta, epilepsy or idiocy have no relationship to the great majority of cases of enuresis I carefully into the question of spina bifida occulta in number of patients Every case of enuresis threadworms was admitted to hospital and given t ment to get rid of the parasites I was never able satisfy myself that they were a causal factor enuresis is more common among the under-nou than the well-nourished it would be surprising if improvement in the diet of the former did not reduce incidence of the complaint The signs of inflammation the neck of the bladder in cases of enuresis are not to be seen by the cystoscopist unless the child is in the lithotomy position, because they are usually present on at and adjacent to the internal urinary meatus would be unreasonable to assume that they are ca by the instrument when an inspection of the poster urethra shows more important inflammatory changes the immediate vicinity The question of how many leucocytes in the urine are to be regarded as evidence of infection is one I am not prepared to debate

Harley Street, W 1 H P WINSBURY-WHITE

SIR,—Dr MacLeod's voluntary and diurnal attack from the heights has damped but not drowned me I am sorry that he found "turbid" a letter which some have found lucid to the verge of the brutal, and surprised that he should have bothered about a criticism which he a little rudely dubs "senseless" and unworthy of a serious reply My question about the relation between dilatation and infection, which seems to have caused him so much annoyance, may be clearer to him if I put it this way if patients have both upper urinary tract dilatation and infection below, how does one know which is primary with enough certainty to divide the cases into two groups ? As to Bartholin's glands, Dr MacLeod will, I hope, forgive me if I refuse to embark on a lecture on elementary anatomy It will save us both a lot of time if he will refer to Gray's "Anatomy"

Whitchurch, Aylesbury RAYMOND GREENE

CARLOS FINLAY AND YELLOW FEVER

SIR,—I am fully satisfied with the general trend of your criticism of my book on my father's work on yellow fever (Aug 9, p 167), but must clear up some misunderstandings in connexion with his experimental cases Owing to their lack of severity and their small number in comparison with the inoculated cases you are right in sustaining that they cannot, by themselves be considered as proof of his theory—this required the later sanction of the more convincing experiments of the U S Army Yellow Fever Commission—but what I consider unjust is the supplementary statement, made in most Anglo-American writings, that he did not produce any positive experimental cases This statement is based solely on the ground that his positive results did not comply with the narrow time-limits fixed by the commission, limits which later investigations have proved not to be as exact as at first supposed As regards the incubation period in man my father's views have always coincided with those of the commission in that yellow fever is only infective in the first days of the disease, protracting the infective period up to the sixth day N P Hudson and C B Philip however, proved in 1929 (*J exp Med* 50, 583) that yellow-fever monkeys are "mosquito-infective" before the appearance of fever, all through the febrile period and even after death As regards the duration of the extrinsic incubation period, J H Bauer and Hudson in 1928 (*Ibid*, 48, 147) showed that the yellow-fever virus can be transmitted through the bite of the mosquito on or after the 9th day Aragão noted in 1929 (*Brazil med* 43, 1481) that one lot of mosquitoes became infective as early as 4 days after ingestion of the virus, and in 1932 N C Davis (*Amer J Hyg* 46, 163) showed that

"1 The extrinsic incubation period of yellow fever in *Aëdes ægypti* was shortened at high temperatures and prolonged at low temperatures

2 The ability to infect was acquired after 4 days at an average temperature of 37° C, after 5 days at 36° C, and 6 days at 31° C

3 When stored at room temperatures averaging 25 1° C *Culex stegomyia* mosquitoes became infective at the end of 8 days, when the room temperature was 23 4° C they were infective when tested at the end of 11 days but not at the end of 9 days

4 Infectivity appeared after 18 days at 21° C

5 Mosquitoes were not infective after 30 days at 18° C "

This shows that the basis of a too short mosquito incubation is wholly insufficient to lead us to discard my father s positive cases in the presence of other data such as proper preliminary isolation clinical symptoms of mild yellow fever (sudden onset, followed by a febrile course with a remission on the second or third day and a final defervescence, accompanied by slowing of the pulse, bleeding of the gums, albuminuria and jaundice), followed by immunity through a span of years of living in a country where yellow fever was endemic It would have been more satisfactory if my father had allowed his infected mosquitoes to incubate longer, but although he realised this possibility as far back as 1891 (p 78 of my book) conscientious scruples held him back, limiting his objective to the immunising of his inoculated subjects by mild attacks of yellow fever, even if this meant that his findings were not always convincing to others

Havana C E FINLAY

GRADUATION AT AN EARLIER AGE

SIR,—Dr Paterson's article leaves me a trifle perplexed Surely the bright boy can still matriculate at 16 take his first M B examination from school or from technical college and enter his medical school at 17 Is it true that he is now *compelled* to wait until 18 or 19 before starting his medical training at all ? There are some for whom it is financially necessary to complete their training as soon as possible Such was my own position and I would therefore think it a pity to force those in like case to turn to other fields But I would not argue from this that qualification at or about 21 is a good thing For one thing it involves some sacrifice in general education, and for another it forces the individual to assume even during his student years responsibilities for which he may not be sufficiently matured

Dr Paterson states that it is a " psychological fact " that the intellect of a boy of 16 has already been mature for two years I am sorry but I do not believe him unless he is using the word in a sense all his own The term is a hard one to define, intelligence, it has been said, is what a psychologist measures when he measures intelligence but even adopting this pragmatic definition there is evidence to suggest progressive maturation until at least 16 If other aspects of mental life be brought into consideration (and they cannot be left out) the process of maturation continues far longer Indeed, there are matters which one can " learn " at 30 which would be beyond one's scope at 20

In general, therefore, it would surely be better to encourage, though not to compel, the medical student to carry his general education a little further and to qualify a little later Apart from Latin and Greek, I should think that he would benefit from some knowledge of philosophy and statistics which he now sadly lacks ! I agree that this raises the whole question of late marriage, which would surely be better solved by state scholarships on an adequate scale If we are to have in the medical profession those who are really suited to it and not just those whose finances will stay the course, some such subsidy will be necessary anyway

The Cassel Hospital C H ROGERSON

ACUTE POLYRADICULONEURITIS

SIR,—The advancement of medicine must necessarily be associated with the appearance of new terminology, yet today there seems to be a facile tendency for the adoption of nomenclature and phraseology, particularly if highly sounding or of continental origin, without sufficient regard for their soundness or suitability In some instances, this may be due to the inherent inferiority substratum in the British character which permits the belief that native enterprise is of a lesser quality than that of the foreigner One sees this feeling prevalent in most intellectual spheres whether music, art, science or medicine, and one wonders why It was probably this self-effacement rather than the desire for progress which led to the eager adoption in this country of the Basle anatomical nomenclature, a scheme sponsored mainly by a collection of German booksellers to whom such expressions as Astley Cooper's ligament, or Hunter's canal were anathema

The term radiculoneuritis came into prominence about 1916 and may have originated in France Recently, it has been used to refer to a condition generally known as acute polyneuritis Those who employ the new edition do so no doubt because they consider it to be an improvement, thereby indicating indirectly that involvement of the nerve roots is of sufficient importance to warrant its inclusion in the title of the disease whereas in fact it is known that the most evident lesion is found in the extraspinal portion of the nerve tract Thus, Holmes in his series of cases declared that examination of the nerve roots disclosed no abnormality whatsoever and this finding seems to be general It should also be remembered that anatomically the term radicular nerve is often applied to the conjoined portion of the nerve roots formed by the junction of the anterior and posterior roots An inflammatory lesion affecting this portion of the nerve tract could quite properly be called radiculoneuritis Thus the term itself can hardly be considered an improvement on anatomical or pathological grounds, nor does the clinical side furnish any additional support The picture of an acute spreading paralysis may be produced by some half-dozen conditions all of which show certain changes in the spinal cord This finding applies also to acute polyneuritis in which the toxic process shows a selective affinity for the neurone as a whole, so that the term polyneuronitis as suggested by Russell Brain is in this respect more suitable But in the absence of a more exact knowledge concerning the nature of the malady there seems little point in substituting one inadequate designation for another even though it may sound more modern

London, S W 3 J H MULVANY

LIGATION OF PATENT DUCTUS ARTERIOSUS

SIR —To those cardiologists whose enthusiasm has been fired by the brilliant exploits of some of our thoracic surgeons, I commend the perusal of a thoughtful and temperate address on the Newer Surgery of the Heart and Large Vessels by H M Marvin (*Bull N Y Acad Med* October, 1941) The operation mortality of ductus ligation in these American cases is astonishingly low—only 4 operation deaths out of 42 cases Nevertheless, like Mr Mulvany, I wonder if this operation is often justified Surely the predisposing factor towards bacterial endocarditis in these, as in other cases is the presence of an avascular bed, on which bacteria and fibrin are deposited from the blood-stream Ligation of the ductus can only modify the conformation of this avascular bed, and in any case by the time the diagnosis is made bacteria and clot have probably already been implanted in the pulmonary artery opposite the entrance of the ductus I agree again with Mr Mulvany in the possibility of an arrest and perhaps of cure of bacterial endocarditis in these patients without surgical treatment I have at present under my observation a lady who has been symptomless and working since September, 1940, after treatment in February, 1940, with heparin and a sulphonamide of a bacterial endocarditis implanted on a patent ductus

With regard to the non-infected case, it will be interesting to see what is the expectation of life where ligation has been performed during infancy or childhood But we may have to wait for many years before evidence is convincing that life is prolonged by this somewhat hazardous operation

London, W 1 MAURICE CASSIDY

VITAMIN E

SIR —In your leading article of Aug 23 you reviewed the literature on vitamin E in the treatment of muscular dystrophy and motor-neurone degenerations Your conclusions were that vitamin E is of little practical value, though " that there is something behind this no-one can doubt " The leading article in the *British Medical Journal* this week states " We find nothing yet to persuade us that any human disease or any disturbance of childbearing or locomotion in man is due to a deficiency of vitamin E, or is alleviated by treatment with it " I have read again the papers on which these two leading articles were chiefly based, and I cannot agree that they justify any statement that vitamin E is of little or no value To avoid repetition I shall only examine in detail those papers dealing with muscular dystrophy since the same criticisms are applicable in part to the papers on nervous degenerations and, indeed, to the treatment of all deficiency diseases

In muscular dystrophy some muscle-fibres are normal, some are completely replaced by fibrous tissue, and some are degenerating but are still present It is only the function of these latter fibres which can be improved by any form of treatment In children getting worse rapidly there are many such fibres, and so a great improvement is possible In adults, in whom the disease has been slowly progressive for many years, there are only a few degenerating fibres present at any one time The muscular weakness is essentially due not to these fibres but to the loss of those which have completely degenerated during the long course of the illness In adults, therefore, little or no improvement is ever possible, though the disease can be arrested ' Bearing these facts in mind the negative results of vitamin-E therapy reported from the Mayo Clinic (Eaton, L M , Woltman, H W and Butt, H R *Proc Mayo Clin* 1941, **16**, 523), by M M Doyle and H H Merritt (*Arch Neurol Psychiat* 1941, **45**, 672), and by G Fitzgerald and B McArdle (*Brain*, 1941, **64**, 19) lose much of their significance, since in a total of 20 cases treated only 5 were children J W Ferrebee, W O Klingman, A M Frantz (*J Amer med Ass* 1941, **116**, 1895), however, have also reported negative results in a series of 13 children, so that there are 18 cases in all which have not responded to treatment These, numerically, are more than balanced by the children who have improved, according to S Stone (*J Amer med Ass* 1940, **114**, 2187 , *J Pediat* 1941, **18**, 310), G E Donovan (*Lancet*, 1940, **2**, 162) myself, and various personal communications from England and abroad There are several explanations of these contradictory reports

importance of not giving too much vitamin E—All the children who have improved have been given vitamin E either as whole wheat germ or as wheat germ oil and yeast, the amounts not greatly exceeding those which could be taken in food The children who have not improved have all had synthetic vitamin E as well as, or instead of, the natural forms, and the total amount taken has been very large Most of the children, indeed, received so much vitamin E that they could only have obtained the same amount from their diet had they eaten each day three times their own weight of bread from which the wheat germ had not been removed It seems most unlikely that these amounts of vitamin E can ever be required, while it does seem likely that they are harmful For the muscles themselves probably destroy any surplus of vitamin E, and therefore their degeneration is likely to be hastened when they are confronted with the strain of destroying amounts of vitamin E many times as large as could ever be provided by any diet

importance of giving other vitamins and zinc and manganese in their correct proportions—There should be some relationship between the amounts of the various vitamins, and also minerals, in the diet For instance the storage of vitamin A is affected by vitamin E, vitamin D needs a certain calcium phosphorus ratio to develop fully its antirachitic activity, and there is an optimum ratio between manganese and vitamin B for preventing the toxic effects which occur when large amounts of either are taken It seems that those minerals and vitamins which are especially necessary to each other for their mutual metabolism by the animal body generally occur together in vegetable foods So though we do not know enough to give the correct balance of vitamins and minerals by synthetic preparations, we can solve the problem when treating deficiency diseases by giving foods very rich in the particular vitamin the deficiency of which is causing the symptoms In this way we shall automatically keep the correct proportions of the related vitamins and minerals and avoid the risk of excessive doses In the case of vitamin E whole wheat germ is the best preparation, containing not only the B complex but also zinc and manganese, the distribution of the last two in foods being the same as that of vitamin E Looked at from another point of view, once one postulates a deficiency of vitamin E one must also postulate a deficiency of all those substances chiefly found with vitamin E, and so one must give them as well

importance of treating sepsis—Any mild chronic or recurrent sepsis, such as carious teeth or frequent colds, completely prevents any response to vitamin E therapy Probably the absence of any sepsis would have been emphasised in the negative reports on the value of vitamin E had its importance been realised As sepsis is not mentioned in these reports it seems possible some children failed to respond because of some mild infective focus

The disordered creatine metabolism of muscular dystrophy has been investigated by Fitzgerald and McArdle in 2 children for periods of 26 and 36 days respectively, and by Ferrebee, Klingman and Frantz in 2 children for 10 days Vitamin E given throughout the investigations did not improve the metabolism of creatine This was to be expected, partly because clinical improvement seldom occurs in under eight weeks and partly because the children were receiving excessive amounts of synthetic vitamin E

Wimpole Street, W 1 FRANKLIN BICKNELL

DAY NURSERIES

SIR,—Your report in last week's issue of the conference on day nurseries shows that a point was raised there which has usually been ignored in the past, and which in my opinion is not being stressed sufficiently even now Most child psychiatrists would agree with me that the child's greatest need during its earliest years is for a mother's affection and attention This is essentially a strongly *personal* relationship and cannot be adequately replaced by any nursery school however well run Marguerite Dobbing's experience, as given in her letter to the *New Statesman*, is another discovery (however belated) of a truth that has been preached by child-guidance workers for some years Miss Anna Freud hit the mark when she said, "Nursery schools had never been meant as a substitute for the home any more than welfare clinics did away with the need for the mother's care or child guidance clinics with the need for education by the parents" The nursery school is not a home, and even a bad home is better than no home at all The intuitive understanding on the part of mothers of this relationship with their children has a great deal more to do with the slow progress of the nursery-school movement than is generally appreciated Just as many a mother, quite rightly in my opinion, clung to her child when the evacuation scheme was launched, so today she will only use the nursery school as a last, often desperate, resort The care of an aunt or granny, as your report implies, is preferred as being more satisfactory (With regard to evacuation, many a mother has told me "I just couldn't send him away, he would never get over it")

We must recognise that the break-up of family life occasioned by the war is a serious evil and not the least serious outcome of war conditions I agree with Anna Freud that the nursery schools are trying to fill a serious gap, but we must admit it is only a second best (There is a real danger that they may be used to blanket those essential social and economic reforms which are so seriously needed to maintain an adequate family life) With her, I would plead for some place to be found in the security scheme for the mother herself For only in the security of the intimately personal relationship between mother and child can the child develop a real and stable character

If further confirmation of these views were needed it is to be found in the experiences of the Jewish communal colonies in Palestine There both mother and father work (on the land) and the children are cared for communally by skilled nurses None the less, it has been found necessary, in order to get the best results, to allot definite times each day when the parents can take charge of their children I recommend a study of the development of these communal nurseries to all interested in child welfare

Leeds H EDELSTON

TOWARDS A NATIONAL SERVICE IN CLINICAL PATHOLOGY

SIR,—Dr Ponder's statement that the "comprehensive pathological service" now functioning in the county of Kent is "very much on the lines indicated" is hardly correct The view expressed and reiterated by myself was that by its very nature clinical pathology can only properly be practised "in laboratories forming an integral part of a large and active hospital", that it can only function properly "in a laboratory which is part of an institution for the treatment of the sick", and further that it can only properly be practised by those in close and continuing touch with clinical work On his showing the service described by Dr Ponder meets neither of these fundamental requirements

Wolverhampton S C DYKE.

Public Health

Health of New Zealand

THE annual report for 1940–41 of Dr M H Watt, director general of health records an exceptionally healthy year in an exceptionally healthy part of the world where public medicine has reached a high level of efficiency and is extending towards a complete national medical service The European population of New Zealand in mid 1940 was 1,546 312, its birth-rate was 21 2, the highest rate since 1925 and its death-rate 9 25 against 9 2 in 1939 Infantile mortality, for which New Zealand has long held the blue riband of the world sank to the record low level of 30 2 Of the 990 infants who died in the year, 521 failed to survive a week and 630 failed to survive a month The neonatal mortality has remained almost unaltered at about 22 5 per 1000 live births for many years Rather more than half of the deaths within the first month are certified as due to prematurity alone, but since prematurity is not per se a cause of death this means that about half of the neonatal mortality is unexplained and in the present state of our knowledge is inexplicable Tuberculosis mortality was 388 per million, which is a low record for New Zealand, and we believe for any community exceeding a million Cancer mortality, at 1202 per million, would on standardisation for age and sex work out to be not much different from our rate of 1600

The statistics of the Maori population tell a different story Their birth-rate was 48 9, infantile mortality 87 2, crude death-rate 17 5 and tuberculosis mortality 4132 per million Excluding tuberculosis, the death-rate among Europeans would be 8 86 and amongst Maoris 13 37 so tuberculosis alone accounts for not quite half of the higher death-rate among the Maoris Until recently, the native population of New Zealand unlike those of the African dominion colonies and protectorates was little infected with syphilis but this has changed for the worse in some districts The health department is fully alive to this and is taking active steps to combat the spread of syphilis among the Maoris

Among the many interesting sections in the report is that dealing with hydatid disease, which is probably more common in the islands—especially in the South—than in any other part of the world There are about 120 new cases with 16 deaths each year, and the incidence does not decrease When we hear that about half the sheep and cattle in New Zealand have livers or lungs infected with hydatid cysts and more than a third of the country dogs harbour the adult *Tænia echinococcus*, we do not wonder at the frequency of the human disease, or why it does not diminish Measles, which three years ago spread over New Zealand in epidemic form of exceptional severity for modern times, caused but one death in 1940

Infectious Disease in England and Wales

WEEK ENDED NOV 1

Notifications —The following cases of infectious disease were notified during the week smallpox 0, scarlet fever, 1204, whooping-cough 1955, diphtheria 915, paratyphoid, 35, typhoid 20, measles (excluding rubella) 624, pneumonia (primary or influenzal), 553, puerperal pyrexia, 118, cerebrospinal fever, 102, poliomyelitis 23, polio-encephalitis, 1, encephalitis lethargica 2, dysentery, 123, ophthalmia neonatorum, 79 No case of cholera plague or typhus fever was notified during the week

The number of civilian and service sick in the Infectious Hospitals of the London County Council on Oct 29 was 1296 including scarlet fever 165 diphtheria, 297 measles 22, whooping cough 492, enteritis 21 chicken pox 31 erysipelas 25, mumps 5 poliomyelitis 6 dysentery, 27 cerebrospinal fever 10 puerperal sepsis 12, enteric fevers, 36 german measles 1 other diseases (non infectious), 81 not yet diagnosed, 65

Deaths —In 126 great towns there were no deaths from scarlet fever, 2 (0) from enteric fevers 2 (0) from measles 9 (3) from whooping-cough 22 (1) from diphtheria, 59 (3) from diarrhœa and enteritis under 2 years and 11 (1) from influenza The figures in parentheses are those for London itself

There were 7 deaths from diarrhœa at Manchester, 5 at Liverpool and 5 at Birmingham

The number of stillbirths notified during the week was 157 (corresponding to a rate of 32 per thousand total births), including 17 in London

MEDICINE AND THE LAW

The Diabetic Motorist

THE Belfast magistrate has dismissed an application by the police that a diabetic doctor should be deprived of his driving licence The police contended that the reactions to medical treatment rendered the patient unfit to have proper control of a car The physician to the biochemical department of the Royal Victoria Hospital giving evidence for the motorist expressed the view that provided diabetes was properly controlled by insulin, there was no reason why the patient should suffer incapacity from insulin coma, he himself had some 3000 patients under treatment including, along with many private motorists, bus drivers and engine drivers, and had no reason to suppose them a danger to traffic The magistrate, observing that this was the first case of the kind in his experience, was not prepared to give effect to the application of the police and in effect disqualify possibly thousands of drivers who use the roads today with as much safety as persons who do do not suffer from diabetes

The law in Northern Ireland is much the same as in Great Britain According to section 5 of our Road Traffic Act of 1930 an applicant for a driving licence must “ make a declaration in the prescribed form as to whether or not he is suffering from any such disease or physical disability as may be specified in the form or any other disease or physical disability which would be likely to cause the driving by him of a vehicle to be a source of danger to the public ” If from the declaration it appears that the applicant does suffer from any such disease or disability the licensing authority must refuse the licence The form as last prescribed in 1937, asks the applicant specifically to declare epilepsy or sudden attacks of disabling giddiness or fainting, any defect in movement, control or muscular power of either arm or leg or any other disease which would be likely to cause his driving to be a source of danger to the public While the police are quite entitled to prove if they can, that a particular diabetic is unfit to drive, it would not seem proper to allow them to insert (in effect) the word “ diabetes ” in the prescribed form along with the word “ epilepsy ” if the Minister of Transport (or his equivalent in Northern Ireland) has not done so

Obituary

FRANCIS CHARLES MARTLEY

M D CAMB F R C P I D P H

DR Martley, who died on Nov 2 at the age of 76, will be best remembered for the part he played in the welfare of the Medical Sickness Annuity and Life Assurance Society He was vice-chairman of the society in 1908 before it became a mutual assurance company and in 1930 was elected chairman of the board of directors holding this office until his death He had a quite unusual ability for figures and correlation of facts and though the small amount of Irish in his make up was occasionally evidenced by a provocative remark, it meant nothing for behind it one could see a kindly pair of eyes and a hidden smile No-one could have laboured longer or more faithfully than he did for the society, the success of which was a source of great satisfaction to him, and his wise counsel will be greatly missed

Francis Charles Martley was born in Dublin and was educated at Rugby and Cambridge, where he took the natural sciences tripos in 1887 He entered St Mary’s Hospital with a science exhibition, qualifying in 1890 and later taking many higher diplomas After being house-physician at St Mary’s and practising for a while at Buckhurst Hill, he went back to Dublin as demonstrator of chemistry at the R C S I and anæsthetist to St Stephen’s Hospital In 1908, however, he returned to London as assistant in the inoculation department at St Mary’s where he remained on the active staff for thirty years At first he was largely engaged in teaching workers from all parts of the world, who came to learn about the opsonic index In later years he was chiefly interested in blood grouping and carried out some research bearing on its value in paternity cases in the course of which he made the interesting observation that group two (Moss) corpuscles phagocytose some 25% more bacteria than do group four corpuscles

Dr Martley married in 1892 Adelaide Amelia Strangman who predeceased him in 1935 He leaves a son and two daughters

STUART ALEXANDER TIDEY

M D LOND, M R C P, S F D

Dr Stuart Tidey, who died on Oct 29, at the age of 84, was born in Reading His father was an artist and his childhood was spent largely at schools in Corsica, Switzerland and Germany He studied engineering at the Crystal Palace for two years before he entered St Mary's Hospital where he graduated in 1886, later taking the M D Lond, the M R C P and the Swiss federal diploma after further study at Geneva He had held the posts of H S and assistant pathologist at St Mary's, and in 1890 he started practice in Montreux, remaining there until 1912 except for a brief interval in Florence, where he followed StClair Thomson At Montreux he had a large practice both on the lakeside and at the climatic stations on the hills above But his health giving cause for anxiety he went to settle in British Columbia where after farming for a bit he took the state diploma in medicine and joined John Antle's medical mission to loggers The last war found him though already 56, ready for fresh work, and he helped to fit out the hospital ship *St George* and worked there till 1917 when he joined the medical staff of the Middlesex War Hospital, near St Albans Still spoiling for adventure he served 1920–31 as ship's surgeon for the Elders & Fyffes line Very quiet and rather rugged in manner, L P writes he always knew his job and the latest developments in it He would come almost unobserved into a medical board at Napsbury and almost immediately he would say the few words making points that were in danger of being missed His writings were few for a man of his originality and vigour, apart from some handy guide and travel books he published his experience of the use of compression in pulmonary lesions and of the drainage of empyema He loved to discuss these matters and specially enjoyed any argument against his own theories

At the age of 73 Tidey retired to Edgware where he could indulge his tastes for music natural history and gardening The progress of parkinsonism curtailed his physical activities, but he retained his mental alertness to the last He married Georgiana Booth, who predeceased him, and leaves two daughters

THE CASE HISTORY IN DIAGNOSIS

J. PLESCH M.D. BERLIN, L.R.C.P.E.

DIAGNOSTIC methods employed in medicine have advanced but insufficient attention has been paid to the importance of the case-history. If we do not discuss his case with the patient we bring medicine to the level of veterinary medicine. In giving a history the patient finds or loses his confidence and discovers whether he is dealing with merely a man who has studied medicine or with a real doctor. We are led towards a diagnosis by the history of the patient and his illness, by the first impression we get of him and by every fact which our senses are capable of observing. these put us on the right track for deeper exploration of his illness. Diagnosis depends on association of ideas. Neglect of history-taking springs from the rapid development of factual knowledge and of objective methods of examination by physical chemical bacteriological and microscopic means. We have lost confidence in our intuitive abilities and do not use or rely on our five senses sufficiently. this is regrettable because medicine must always remain an art to which science is only the servant. In medicine we try to judge the relations of the various functions to each other, it is impossible to reach a diagnosis according to a mechanical scheme. Our judgment must depend partly on imaginative intuition and we can only pass on to the student the method of making the bricks from which he must build the diagnosis.

Even in many teaching hospitals case-histories consist only of notes on age and sex diseases of childhood a few remarks on the family the symptoms of the onset of the present illness and a brief account of a superficial examination. Recent work on constitution and heredity and on significant psychological findings is ignored. Usually there is a description of the patient's height, physical development and colouring—in these days of photography. Even the passport office has replaced written descriptions by photographs. Simple photography, coloured photography and the cinematograph can tell more about family likeness constitution complexion temperament and anomalies than any words. They also make it possible to record changes over a period.

History taking must be accompanied by inspection because the first impression directs investigation. We must also note any constitutional and psychological anomalies. The conditions of the extremities may disclose the duration of the illness. a soft sole of the foot indicates long illness tough palms hard work · the wrinkles of the face betray whether the temperament is gay meditative choleric or depressed. clothing jewellery, or a tattoo mark all give something away. A small telangiectatic mole in the occipital region a third nipple like a wart but erectile hypospadias cryptorchism, relics of gillclefts polydactyly and birthmarks all have their psychological projections. Illnesses take a different course in patients with such embryological anomalies. A woman with masculine traits recognisable by hairs of the pudenda reaching up to the navel has an entirely different psychical make-up from a woman whose dermatographia shows her extreme femininity. The family history must not be confined to parents and brothers sisters and children. Mendel's law demands that we should inquire further. It is not so easy to get at the truth about relations since patients generally dislike disclosing other people's secrets. or the information may be inaccurate because the patient takes a flattering view of his family. Illegitimacy is seldom admitted. It is more difficult still to get at the truth about the patient himself. Exaggeration, understatement, distortion are not always intentional, they often occur because the patient is usually not at all clear about himself, inquiry then becomes a psychoanalytical examination. If we suspect insincerity, or that the patient is trying to disguise the facts, we must get at the truth by clever cross-examination. When the patient becomes aware of his tactical inferiority he will quickly change his attitude and become more confiding. We must, however, make use not only of the facts he tells us but of the lies, for they betray his weaknesses and are sometimes more revealing than the facts themselves.

* * *

A history of previous illness is as a rule difficult to verify. Acidity, liverishness nervousness indigestion rheumatism and similar ambiguous expressions are used freely. Pains are misleadingly related to various organs —backache to the kidneys and sensations in the chest to the heart. The patient must be induced to describe his symptoms and it is pleasing to find how readily even uneducated patients choose the right words how comprehensibly they describe a cramp the sudden onset and gradual fading of a colic the pain of angina pectoris or the distress of an asthmatic attack. By watching the patient closely as he tells his story by noting his complexion and his gestures, we may find a short cut to the understanding of his trouble. At this stage he tells us what he himself thinks important. It may have little bearing on the essential disease but we must pay attention to it in order that he may give vent to his feelings. "Les hommes avec le petit papier" described by Charcot. are found not only among the hyperthyroid, we must let them make their points but circumlocution can be avoided by adroitly placed inquiries for other symptoms.

We must of course be cautious in accepting the patient's estimates of size or quantity. The appetite is always measured by comparison with the appetite of those about him the state of the bowels by the number. not the size, of the actions. sweating is reckoned in changes of nightwear. it is difficult to get any estimate of the daily urine. hæmorrhage will be counted by the size of the vessel in which it is emptied, sputum is always a cupful. menstruation is estimated by the number of changed towels.

Few events are more significant in physical and psychical development than adolescence. The less disturbance there is during this transitional phase the more likely is the later sexual life to be normal and vice versa. An otherwise incomprehensible illness may be explained by hormonal imbalance in those whose adolescence was disturbed. Delicacy and skill are needed to get truthful information about the sexual life but a full inquiry will often evoke surprisingly rapid improvement in neurotic cases.

Have we perhaps overrated the value of objective methods of examination? Examination of organs or systems will enable us to localise the change in them but it is merely a form of diagnostic sport to be able to assert that somebody died from cirrhosis of the liver, from pulmonary tuberculosis or from valvular disease. What we ought to find out is how it was possible for the patient to go on living at all before his cirrhosis, his tuberculosis or his incompetent valves killed him. This will teach us what adjustments the body makes to its diseased organs and may point the way to compensatory treatment. We are turning nowadays from the study of dead pathology to that of living function from the organs to the organism.

Physiology is only concerned with conditions in the normal body and experiments often deal with such extreme states as starvation or of utter repletion—of intense activity of functions or of almost complete arrest. Experiments on organs and tissues in vitro are still too often taken to represent the actual processes in vivo. Such investigations cannot mimic the coördinated automatic and compensatory mechanisms which operate in the living organism, they are only the separate stones in the mosaic. They do not show what made life possible when an organ was grossly damaged. Restitutio ad integrum is a rare thing in pathology, our treatment must aim at supporting the body's natural compensating mechanisms.

* * *

Collectively men can be regarded as statistics, but in practice the doctor must know the idiosyncrasies of each patient so that for example he can tell whether in an epidemic of typhoid that patient will be one of the 15% of fatal cases or not. In the relationship between the individual and the disease it is the individual who varies. For instance two cases of stomach ulcer of similar size and location will not as a rule, justify the same prognosis or treatment. A full case-history may indicate how and why the patient fell ill, or incurred an accident. There about the opsonic index In later years he was chiefly interested in blood grouping and carried out some research bearing on its value in paternity cases, in the course of which he made the interesting observation that group two (Moss) corpuscles phagocytose some 25% more bacteria than do group four corpuscles

THE CASE HISTORY IN DIAGNOSIS

J. PLESCH, M.D. BERLIN, L.R.C.P.E.

DIAGNOSTIC methods employed in medicine have advanced, but insufficient attention has been paid to the importance of the case-history. If we do not discuss his case with the patient we bring medicine to the level of veterinary medicine. In giving a history the patient finds or loses his confidence, and discovers whether he is dealing with merely a man who has studied medicine or with a real doctor. We are led towards a diagnosis by the history of the patient and his illness, by the first impression we get of him and by every fact which our senses are capable of observing; these put us on the right track for deeper exploration of his illness. Diagnosis depends on association of ideas. Neglect of history taking springs from the rapid development of factual knowledge and of objective methods of examination by physical, chemical, bacteriological and microscopic means. We have lost confidence in our intuitive abilities and do not use or rely on our five senses sufficiently; *this is regrettable because medicine must* always remain an art to which science is only the servant. In medicine we try to judge the relations of the various functions to each other; it is impossible to reach a diagnosis according to a mechanical scheme. Our judgment must depend partly on imaginative intuition, and we can only pass on to the student the method of making the bricks from which he must build the diagnosis.

Even in many teaching hospitals case-histories consist only of notes on age and sex, diseases of childhood, a few remarks on the family, the symptoms of the onset of the present illness, and a brief account of a superficial examination. Recent work on constitution and heredity and on significant psychological findings is ignored. Usually there is a description of the patient's height, physical development and colouring—in these days of photography. Even the passport office has replaced written descriptions by photographs. Simple photography, coloured photography and the cinematograph can tell more about family likeness, constitution, complexion, temperament and anomalies than any words. They also make it possible to record changes over a period.

History taking must be accompanied by inspection because the first impression directs investigation. We must also note any constitutional and psychological anomalies. The conditions of the extremities may disclose the duration of the illness: a soft sole of the foot indicates long illness, tough palms hard work; the wrinkles of the face betray whether the temperament is gay, meditative, choleric or depressed; clothing, jewellery, or a tattoo mark all give something away. A small telangiectatic mole in the occipital region, a third nipple like a wart but erectile, hypospadias, cryptorchism, relics of gillclefts, polydactyly and birthmarks all have their psychological projections. Illnesses take a different course in patients with such embryological anomalies. A woman with masculine traits recognisable by hairs of the pudenda reaching up to the navel, has an entirely different psychical make-up from a woman whose dermatographia shows her extreme femininity. The family history must not be confined to parents and brothers, sisters and children; Mendel's law demands that we should inquire further. It is not so easy to get at the truth about relations, since patients generally dislike disclosing other people's secrets; or the information may be inaccurate because the patient takes a flattering view of his family. Illegitimacy is seldom admitted. It is more difficult still to get at the truth about the patient himself. Exaggeration, understatement, distortion are not always intentional, they often occur because the patient is usually not at all clear about himself; inquiry then becomes a psychoanalytical examination. If we suspect insincerity, or that the patient is trying to disguise the facts, we must get at the truth by clever cross-examination. When the patient becomes aware of his tactical inferiority he will quickly change his attitude and become more confiding. We must, however, make use not only of the facts he tells us but of the lies, for they betray his weaknesses and are sometimes more revealing than the facts themselves.

* * *

A history of previous illness is as a rule difficult to verify. Acidity, liverishness, nervousness, indigestion, rheumatism and similar ambiguous expressions are used freely. Pains are misleadingly related to various organs—backache to the kidneys and sensations in the chest to the heart. The patient must be induced to describe his symptoms, and it is pleasing to find how readily even uneducated patients choose the right words, how comprehensibly they describe a cramp, the sudden onset and gradual fading of a colic, the pain of angina pectoris or the distress of an asthmatic attack. By watching the patient closely as he tells his story, by noting his complexion and his gestures, we may find a short cut to the understanding of his trouble. At this stage he tells us *what he himself thinks important*. *It may have little* bearing on the essential disease, but we must pay attention to it in order that he may give vent to his feelings. "Les hommes avec le petit papier" described by Charcot are found not only among the hyperthyroid; we must let them make their points, but circumlocution can be avoided by adroitly placed inquiries for other symptoms.

We must, of course, be cautious in accepting the patient's estimates of size or quantity. The appetite is always measured by comparison with the appetite of those about him, the state of the bowels by the number, not the size, of the actions; sweating is reckoned in changes of nightwear; it is difficult to get any estimate of the daily urine; hæmorrhage will be counted by the size of the vessel in which it is emptied; sputum is always a cupful; menstruation is estimated by the number of changed towels.

Few events are more significant in physical and psychical development than adolescence. The less disturbance there is during this transitional phase the more likely is the later sexual life to be normal, and vice versa. An otherwise incomprehensible illness may be explained by hormonal imbalance in those whose adolescence was disturbed. Delicacy and skill are needed to get truthful information about the sexual life, but a full inquiry will often evoke surprisingly rapid improvement in neurotic cases.

Have we perhaps overrated the value of objective methods of examination? Examination of organs or systems will enable us to localise the change in them, but it is merely a form of diagnostic sport to be able to assert that somebody died from cirrhosis of the liver, from pulmonary tuberculosis or from valvular disease. What we ought to find out is how it was possible for the patient to go on living at all before his cirrhosis, his tuberculosis or his incompetent valves killed him. This will teach us what adjustments the body makes to its diseased organs, and may point the way to compensatory treatment. We are turning nowadays from the study *of dead pathology to that of living function*, from the organs to the organism.

Physiology is only concerned with conditions in the normal body, and experiments often deal with such extreme states as starvation or of utter repletion—of intense activity of functions or of almost complete arrest. Experiments on organs and tissues in vitro are still too often taken to represent the actual processes in vivo. Such investigations cannot mimic the coordinated, automatic and compensatory mechanisms which operate in the living organism; they are only the separate stones in the mosaic. They do not show what made life possible when an organ was grossly damaged. Restitutio ad integrum is a rare thing in pathology; our treatment must aim at supporting the body's natural compensating mechanisms.

* * *

Collectively men can be regarded as statistics, but in practice the doctor must know the idiosyncrasies of each patient so that, for example, he can tell whether in an epidemic of typhoid that patient will be one of the 15% of fatal cases or not. In the relationship between the individual and the disease it is the individual who varies. For instance, two cases of stomach ulcer of similar size and location will not, as a rule, justify the same prognosis or treatment. A full case-history may indicate how and why the patient fell ill, or incurred an accident. There may be some incipient nervous disorder which delayed reaction time, or impaired coordination, or accident may be coupled with early signs of tabes or cerebral tumour, syringomyelia, arteriosclerosis, arthritis, or ocular or aural diseases. The case-history may throw light on such integrative functions as complexion, respiration, pulse, appetite, sweating, temperature, sleep, posture, gait, and weight.

The best way to assess the state of a function is to suggest to the patient an exercise which calls on that function and to watch his reaction to the suggestion. Thus one asks a man with cardiac insufficiency (even though he shows hardly any sign of it when at rest) whether he could run up five flights of stairs—the look of astonishment on his face will indicate plainly enough the presence of cardiac damage. The mere thought of the effort makes him profoundly anxious. The information derived from a test-meal is meagre compared to that which we may gather by talking to the patient about his favourite dishes. Offered a glass of melted butter, a man with high gastric acidity would accept it, whereas a man with hypo-acidity would register disgust at the mere thought. The psychophysical reflex is so graded that one might almost speak of "psychological titration" of the stomach juice.

But we must realise that our relation to the patient is reciprocal; we analyse him by his answers, he analyses us by our questions. It is this psychoanalysis of the psychoanalyst which creates mutual confidence and, alas, also disappointments. The task of history-taking is too important to be left to the younger members of the staff. A broad view, readiness to understand and sympathise, kindliness, ability to judge without severity, to encourage, instruct, advise and attract—all these are needed in the taking of a case-history, and in no phase of medical activity are experience and knowledge more necessary.

POLISH FACULTY OF MEDICINE AT EDINBURGH UNIVERSITY

AT the Royal Society of Medicine on Nov. 5 Prof. A. T. Jurasz, dean of the Polish Faculty of Medicine within the University of Edinburgh, addressed the history section on the foundation and achievements of the faculty. He described the events which led up to the creation of this university within a university. The occupation of Poland lost the Poles their academic institutions, research centres and libraries, and exterminated the cultural life of Poland as a whole. The Polish Medical Faculty was to a certain extent symbolic of the need for all countries to maintain the standards of Western culture in the face of the destructive power of Nazi Germany. The faculty was formed by the unanimous resolution of the Medical Faculty of Edinburgh, followed by the acceptance of the scheme by the senate; the inaugural ceremony, in the presence of the President of the Polish Republic, took place on March 22, 1941. The first academic year was rather concentrated because there were no holidays. It was carried through without a break, and the second year has now started. The enrolments in the first year were 77 and in the second year 120 students. The first person to graduate was a Polish officer-pilot in the R.A.F.; he took part in many flights over Germany, but nevertheless found time to prepare for his final examination. During the last academic year 640 hours of lectures were given for the first-year students, and 1160 hours for the fourth and fifth years. The laboratories, the lecture-theatres and the wards of the various institutions of the university are open to the Poles. Professor Jurasz suggested that something more than mere chance had determined that Edinburgh should become the seat of the faculty. There were old cultural links between the two countries. In the 18th and 19th centuries Scots came to Poland. Later Edinburgh University became a cultural centre for many prominent Poles, and they used the experience gained in Scotland in founding clinics and scientific institutions in Poland, and even in reforming the teaching of medical science in the University of Cracow. The foundation of the faculty was symbolic of the collaboration which would exist after the war.

Dr. J. F. Halls Dally, president of the section, pointed out that however much help had been given by others, Professor Jurasz was essentially responsible for the success of the enterprise. Dr. E. Ashworth Underwood suggested that after the war it might be possible to establish a small British faculty of medicine in various continental universities thus permitting certain students to finish their studies abroad—and acquire a practical knowledge of the language and culture of the people among whom they resided. Sir Alfred Webb-Johnson expressed his great interest in the unique Edinburgh experiment, and Dr. W. Clarke Trotter discussed the historic relations between Poland and the University of Edinburgh.

The address was preceded by a small luncheon in honour of Professor Jurasz, and after the meeting a reception was given by the Polish Ambassador at the Embassy.

FAREWELL, CHOCOLATE SOLDIER

THE American Army has exchanged the chocolate ration of the soldier in the field for five pieces of hard candy, individually wrapped and in assorted flavours (*J. Amer. med. Ass.* 1941, **117**, 941). Recent fatigue tests at Minnesota University have shown that men have a greater energy output if they take sugar periodically through the day rather than in large quantities at meal times.

Sugar for the Services,
Candy for the troops—
A soldier shorn of sugar
Invariably droops.

If you want your soldiers
Stiffened at the waist
Give them sugar candy,
Flavouring to taste.

Forget Papa's instructions,
Forget Mamma's appeals—
The energetic soldier
Must eat between his meals.

MIDDLE INCOMES AT BRISTOL

THEIR honorary staffs have lately asked the Bristol voluntary hospitals if they will in future rigidly observe the B.M.A. scale. This means that except in emergencies nobody above the following income limits will be admitted to the general wards or outpatient departments of the hospitals:

£312 married with dependants
£260 married without children
£208 single without dependants

The Bristol Hospitals Fund recognises the doctors' right to fix the line of income-demarcation above which they cannot afford to treat patients for nothing, and it also recognises the difficulties of those with incomes just above the scale, who can afford to pay for most of their medical treatment but cannot find the fees of specialist and surgeon. Anticipating the Nuffield provident scheme the fund has devised what it calls an intermediate contributory scheme. The name is dictated by ambition for it is hoped soon to start yet another scheme for those with still larger incomes. The intermediate scheme was launched by Mr. Egbert Cadbury at a meeting of the fund last July. The fund has made an arrangement with the Bristol voluntary hospitals, by which intermediate members for the payment of 6d. a week can provide for consultation, operations and treatment for themselves and their dependants. People within the following income limits are eligible:

£416 married with dependants
£364 married without children
£260 single without dependants

The only exception to this arrangement is the Bristol Eye Hospital, and even here a modified scale of fees has been arranged for members of the scheme. The scheme can only be operated through the fund.

The fund, as a contributory scheme, has no legal power to make grants to medical staffs, and the board of each hospital is therefore recommended to make a grant to their medical staff fund equivalent to a third of the amount they receive from the fund for treating the intermediate contributory scheme patients. The staff will also receive a quarter of any surplus that may accrue.

ORIGINAL ARTICLES

THE COMMON SULPHONAMIDES

NOMENCLATURE, STRUCTURE AND USES

DENNIS G ARDLEY, M P S

WITH the inevitable increase in the number of compounds introduced into clinical practice for the chemotherapy of bacterial infections the need of an accurate and uniform nomenclature becomes urgent Few modern British books on general medicine or the specialties make any attempt to achieve accuracy in the names used for these compounds, and the medical journals and encyclopædias tend to pander to the whims of their contributors instead of exerting strict control over the names employed As a consequence, for example, all the names which happen to have been employed for the same chemical compound by various contributors to a textbook may appear in different parts of the index Abstracts of articles from foreign journals often use for drugs names which are unfamiliar to readers in this country and in this way the chief point of the abstract may be lost Conversely, proprietary names and erroneous nomenclature in English articles duly find their way into foreign abstracts to the mystification of readers The practitioner who writes a prescription for "sulphonamide," ½ gramme tablets, or the surgeon who orders a wound to be dressed with sulphonamide powder does not realise that what he has ordered is meaningless The writer of an article who describes the treatment of a patient with "Prontosil" given by mouth in such and such a dosage overlooks the fact that there are three distinct chemical compounds to which this name is applied, and that all are given by mouth The limit appears to have been reached by the author of an article on the use of various sulphonamide compounds who calmly announced at the outset that a particular brand name for sulphanilamide would be used to describe all the different compounds employed ! It therefore seems opportune to suggest a few rules for general guidance First, about dosage The common practice of describing oral dosage in terms of number of tablets or volume of a suspension is inadvisable A discussion once arose concerning an article on the treatment of gonorrhœa in which the dosage of sulphanilamide employed was in dispute until it was realised that the author was expressing dosage in drachms of a proprietary suspension Dosage should always be expressed in terms of the active ingredient

Most of the sulphonamides in common use have three kinds of name—a chemical name often occupying a line of print, a scientific synonym or pet-name, being the chemical name in a shortened form, and a various number of trade names The synonym is the one intended for use in scientific articles, but unfortunately not all the compounds have one, and in some cases the trade name is at present unavoidable Whenever possible only the full chemical name or its shortened form should be used, though it may sometimes be convenient to indicate once in an article which particular brand was employed

SULPHANILAMIDE AND ITS EARLIER DERIVATIVES

Sulphanilamide

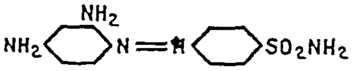
Para-aminobenzenesulphonamide or para-aminophenylsulphonamide is the simplest and most widely used of these drugs, and being the amide of sulphanilic acid the name now commonly adopted of sulphanilamide is at once both accurate and brief, and the employment of proprietary names for this compound in medical literature is inexcusable Of the forty or so trade names indicating proprietary brands of this compound the commonest ones in this country are Colsulanyde, Prontosil album and Streptocide, and sometimes the non-proprietary designations sulphonamide-P or P A B S are used A proprietary brand much used in America is known as Prontylin Some clinicians still do not realise that these names all stand for the same substance, and it is not unusual to hear of a patient's treatment being changed from one make of sulphanilamide to another, because he did not respond to the brand first ordered Many other proprietary names for sulphanilamide, less commonly used than the four already given, are encountered, chiefly in foreign medical literature In table I will be found 42 trade names for sulphanilamide, among which collectors may find choice and rare specimens In the case of a few trade names encountered in foreign medical journals there has been no clue to the composition of the drug, or the composition has been variously described in different articles so that it has been impossible to be certain what the compound was Sulphanilamide was included in the Fourth Addendum to the B P 1932

TABLE I—PROPRIETARY NAMES FOR SULPHANILAMIDE

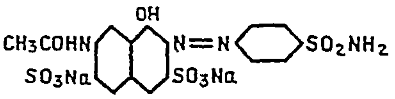
Albosal	Gombardol	Septamide album	Streptocom
Ambesid	Lysococcine	Septanilam	Strepton
Antistrept	Neococcyl	Septinal	Streptozone
Astreptine	Orgaseptine	Septoplix	Sulfamidyl
Bacteramide	Prontosil album	Stopton album	Sulfana
Bactesid	Prontylin	Stramid	Sulfanil
Cepticide	Pronzin album	Strepamide	Sulphanalone
Colsulanyde	Proseptine	Streptamid	Supron
Deseptyl	Proseptol	Streptazol	Therapol
Ergaseptine	Pysoccine	Streptocide	
Erysipan	Rubiazol-A	Streptoclase	

The simplest and most convenient classification of other sulphonamide drugs is to regard them as derivatives of sulphanilamide and as falling into two groups according to whether substitution takes place in the amino (NH_2) or in the amide (SO_2NH_2) portion of the molecule (table II) All the earlier compounds belong to the first class and are split up with release of sulphanilamide in the body. The more active substances introduced subsequently, such as sulphapyridine and sulphathiazole, fall into the second category, and these compounds do not depend for their action on the production of sulphanilamide

The first compound to be employed was sulphonamidochrysoïdin, which is 4′-sulphonamido-2 4-diaminoazobenzene, introduced into commerce under the name prontosil after having been called Streptozon The name prontosil strictly refers therefore to this azo dyestuff but most English clinicians use it to designate sulphanilamide If the word is used at all it should never be employed without qualification, so that there is no doubt as to meaning Sulphonamido-crysoïdin is also known as Prontosil flavum or Prontosil rubrum A less common trade name is Pronzin rubrum A more soluble compound was later introduced for parenteral administration, which consists of a solution of the disodium salt of 4′-sulphonamidobenzene-2-azo-1-hydroxy-7-acetylaminonaphthalene-3 6-disulphonic acid, usually known in this country as Prontosil soluble and sometimes as Prontosil-S or Prontosil II Occasionally the name prontosil is applied to this compound instead of to sulphonamido-chrysoïdin, and in America, where it is given by mouth in place of the latter, it is known under the proprietary name of Neoprontosil, the "descriptive non-proprietary name" proposed for this substance by the Council on Pharmacy and Chemistry of the American Medical Association being azosulfamide The name streptozon has been given to both prontosil rubrum and prontosil soluble, the latter having sometimes been distinguished as Streptozon II or S, and curiously enough the designation Prontosil red is sometimes used for prontosil soluble rather than prontosil rubrum The Rubiazols include the French equivalents of the German azo sulphonamides and rival them in confused terminology It is, however, sufficient to remember that in this country the name rubiazol is applied to a compound which differs from sulphonamido-chrysoïdin in containing a carboxyl (COOH) grouping and hence is conveniently described as carboxysulphonamido-chrysoïdin



Sulphonamido chrysoïdin



Azosulphamide (Prontosil soluble)

In common with most other compounds of the first group in which substitution takes place in the amino

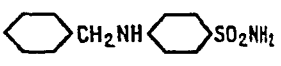
TABLE II

SULPHANILAMIDE DERIVATIVES, AND SULPHONES

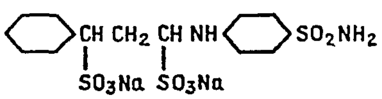
Synonym or abbreviated chemical name	Full chemical name	Proprietary names
SULPHANILAMIDE DERIVATIVES, FIRST CLASS		
Sulphonamido chrysoïdin	4 -sulphonamido 2 4 diaminoazo benzene	Prontosil (flavum or rubrum), Streptozon Pronzin rubrum
Azosulphamide	Disodium 4′ sulphonamidobenzene 2 azo 1 hydroxy 7 acetyl amino-naphthalene 3 6 disulphonate	Prontosil soluble Neoprontosil
Carboxysulphonamido-chrysoïdin	4′ sulphonamido 2 4 diamino-6 carboxyazobenzene	Rubiazol
Benzylsulphanilamide	*p* benzylaminobenzenesulphonamide	Proseptasine (M & B 125) Septazine, 46 R P
Sodium succinyl sulphanilamide	Sodium *p* succinylamino-*benzenesulphonamide*	Ambesid soluble Septinal soluble
None	Disodium *p* (γ phenyl propylamino) benzene sulphonamide α γ disulphonate	Soluseptasine (M & B 137) Soluseptazine, 40 R P
,,	Sulphanilamide lactoside sodium formaldehydesulphoxylate	Sulphanilamide L S F
,,	Sodium 4 sulphonamido-phenylaminoethane α sulphonate	Sulphonamide E O S
SULPHANILAMIDE DERIVATIVES, SECOND CLASS		
Sulphanilyl-dimethyl-sulphanilamide	*p* aminobenzenesulphonamido-benzenesulphondimethylamide	Uleron, Uliron, Ulirone D B 90, D B 373, Diseptal A
Sulphanilyl-monomethyl-sulphanilamide	*p* aminobenzenesulphonamido-benzenesulphonmonomethylamide	Neo uliron, Diseptal B
Sulphanilyl-sulphanil-amide	*p* aminobenzenesulphonamido-benzenesulphonamide	Diseptal C, Disulon
Sulphapyridine	2 (*p* aminobenzenesulphonamido) pyridine or 2 sulphanilylamino pyridine	Dagenan M & B 693, Eubasinium, Septipulmon, Pyriamid
Sodium sulphapyridine	Sodium 2 (*p* aminobenzenesulphonamido) pyridine	Dagenan sodium, M & B 693 soluble
Sulphathiazole	2 (*p* aminobenzenesulphonamido) thiazole or 2 sulphanilylamino-thiazole	Thiazamide M & B 760
Sodium sulpha-thiazole	Sodium 2 (*p* aminobenzenesulphonamido) thiazole	Thiazamide sodium, M & B 760 soluble
Sulphamethyl-thiazole	2 (*p* aminobenzenesulphonamido) 4 methylthiazole or 2 sulphanilyl-amino 4 methylthiazole	M & B 838
Sulphadiazine	2 (*p* aminobenzenesulphonamido) pyrimidine or 2 sulphanilyl-aminopyrimidine	
Sulphacet-amide	*p* aminobenzenesulphonacetamide	Albucid Sulamyd
Sodium sulphacet-amide	Sodium *p* aminobenzenesulphon acetamide	Albucid soluble, Sulamyd soluble
Sulpha-guanidine	*p* amino N guanylbenzenesulphonamide or sulphanilylguanidine	
SULPHONES		
None	Diacetyl 4 4 diamino diphenyl sulphone	Rodilone (1399 F)
,,	4 4 diaminodiphenylglucoside	
,,	Sodium *p p* diamino diphenyl-sulphone N N[1] di dextrose sulphonate	Promin

radical of sulphanilamide, these substances owe activity mainly to the release of sulphanilamide in the body tissues, the coloured compounds being split at the azo linkage Endeavours have been made to show that the azo linkage per se may play a rôle in their action, but all the important recent advances concern colourless compounds, and the dye-stuffs cannot but be regarded as being chiefly of historic interest

Of the sulphanilamide derivatives belonging to the first group which are not dye-stuffs, the most commonly used in England is that formed by substituting one of the hydrogen atoms in the amino group by a benzyl group This compound is para-benzylaminobenzene sulphonamide or benzyl sulphanilamide It is known in England as Proseptasine or M & B 125, and in France as Septazine or 46 R P The drug is soluble in water only to the extent of about 1 in 25,000, compared to sulphanilamide which has a solubility of about 1 in 100 The sodium salt of the corresponding succinyl derivative of sulphanilamide—sodium para-succinylaminobenzenesulpho amide or sodium succinyl sulphanilamide—has bee issued for parenteral administration under the nam Ambesid soluble There is also a product Ambesid, an *it might reasonably be expected that this would* succinylaminobenzenesulphonamide itself, but in fac this is another proprietary name fo sulphanilamide



Benzylsulphanilamide



Soluseptasine

A widely used compound which is much more soluble than sulphanilamide and consequently more suitable for parenteral administration is Soluseptasine or M & B 137, known in France as Soluseptazine or 40 R P I is disodium-*p*-(γ-phenyl-propylamino)-benzene sulphonamide-α-γ-disulphonate, the sodium sulphonate par of the molecule being the solubilising groups No convenient non-proprietary designation for soluseptasine ha come into use

A soluble sulphanilamide derivative for parenter administration, and one having a high *sulphanilamid* content, has recently been placed on the *market* unde the name sulphanilamide L S F It is *described* as sulphanilamide lactoside sodium formaldehydesulphoxylate Reference has also been made to a compound calle Sulphonamide E O S and described as the sodium sal of the ethylsulphonic acid of sulphanilamide I therefore appears to be sodium 4-sulphonamidophenyl aminoethane α sulphonate It has been tried clinicall in cattle and man Mutch (1941) has described som investigations on its pharmacology and activity an has given details of its use in 34 cases of cerebrospina fever

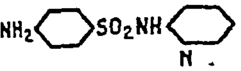
LATER DERIVATIVES

The first drugs of the second class were three disulphanilamide compounds, known originally as Diseptal A B and C, and introduced from Germany Of these the first, and the only one to come into use in England, is known as Diseptal or Uleron It is also calle Uliron, Ulirone, D B 90 or D B 373, and is para amino benzene sulphonamido-benzenesulphondimethylamide o sulphanilyldimethylsulphanilamide Diseptal B is the corresponding monomethyl derivative, and is now referre to in German medical literature as Neo-Uliron Disept C contains no methyl groups, being sulphanilylsulphanilamide Sulphanilyl sulphanilamide is available in Americ and on the Continen under the name Disulon, where it is used in the treatment of gonorrhœa It i also known as “ disulphanilamide,” a name which, unfortunately, has also been used for the dimethyl derivativ (uleron) Claims that uleron is valuable for the treatment of gonococcal, staphylococcal and anaerobi infections have not been substantiated, and the subsequent use of sulphapyridine for the treatment of gonorrhœa and the activity of sulphathiazole in staphylococcal infections have led to its falling into disuse I

Sulphanilyldimethylsulphanilamide (Uleron)

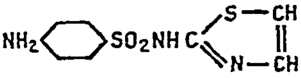
Sulphanilylsulphanilamide

ommon with most other derivatives of the second class leron is not broken down with the release of sulphanil-mide but is eliminated partly unchanged and partly in a conjugated form



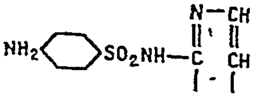
Sulphapyridine

An event of outstanding importance in chemotherapy was the introduction of the compound derived from sulphanilamide by substitution of one hydrogen atom in the amide portion of the molecule by a basic pyridine group, giving 2-(p-aminobenzenesulphonamido) pyridine This was first known as T 693, later introduced as M & B 693 and subsequently called Dagenan, a mutation on an Essex place name To a non-chemist sulphanilylaminopyridine should not be too long to remember but the Americans christened the compound sulphapyridine, which name although not accurately descriptive chemically, has been generally accepted Sulphapyridine proved to have a much higher degree of activity than sulphanilamide, thereby extending the range of chemotherapy far beyond infections by sulphonamide-susceptible strains of streptococci Pneumococcal infections were brought under control, a more potent weapon against gonococcal, meningococcal and gas-gangrene infections provided and the effective chemotherapy of plague and staphylococcal infections brought nearer A calcium compound of sulphapyridine has been placed on the market in Germany under the trade name Orsulon It is issued in tablets for oral administration in the treatment of pneumococcal and other infections In Stockholm a compound of sulphapyridine and salicylic acid, known as salicylazosulphapyridin, and marketed as Salazopyrin, has been used with success in rheumatoid arthritis and ulcerative colitis



Sulphathiazole

An even more active compound than sulphapyridine is the corresponding thiazole derivative 2-(p-aminobenzenesulphonamido) thiazole or 2-sulphanilylaminothiazole, usually called sulphathiazole, and also known in England as Thiazamide or M & B 760, in Switzerland as Cibazol or Ciba 3714, and in France as R P 2090 It has proved its value in the treatment of infections with *Staphylococcus aureus*, some of the clostridia, *Pasteurella pestis*, and various organisms found in urinary-tract infections, including *Streptococcus fæcalis* Various compounds obtained by replacing one of the hydrogen atoms in the thiazole ring have been tried in therapeutics, and of these the name sulphamethylthiazole indicates the 4-methyl derivative—namely, 2-(p-aminobenzenesulphonamido)-4-methylthiazole, or 2-sulphanilyl-amino-4-methylthiazole (M & B 838) Owing to the danger of peripheral neuropathy from the use of these derivatives (cf uleron which also contains methyl groups), and their greater liability to deposit crystals in the urinary tract compared to sulphathiazole itself, little more is likely to be heard of them



Sulphadiazine

Another heterocyclic derivative of sulphanilamide, the pyrimidine analogue of sulphapyridine, has recently been introduced in America, this is 2-(p-aminobenzenesulphonamido) pyrimidine or 2-sulphanilyl-*amino*-pyrimidine Sulphadiazine, as it is called, appears from the preliminary studies of American workers such as those of Finland, Strauss, and Peterson (1941) and of Long (1941) and his associates at Johns Hopkins Hospital to have about the same degree of activity as sulphathiazole and sulphapyridine on pneumococci and meningococci, to have an activity on *Staph aureus*, and to have a high degree of activity on *Klebsiella pneumoniæ* (Friedländer s pneumobacillus) It has been tried in pneumococcal pneumonia, cerebrospinal fever, staphylococcal, streptococcal, gonococcal and other infections but the data at present available concerning its activity, toxicity, absorption, distribution and elimination are inadequate to predict its ultimate place in chemotherapy

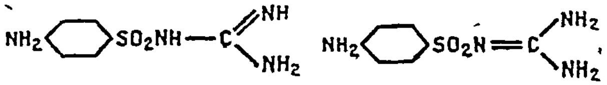
Sulphapyridine and sulphathiazole being of low solubility in water are unsuitable for parenteral administration in solution, for which purpose their sodium salts are employed The latter being compounds of weak acids with a strong base yield solutions which are highly alkaline If one of the amide hydrogen atoms of sulphanilamide is replaced by an acetyl radical the compound p-aminobenzenesulphonacetamide is formed, which is known as sulphacetamide and was introduced under the proprietary name Albucid It has been advocated for use in gonorrhœa, for which purpose it is less effective than sulphapyridine but rather strikingly free from toxic effects, owing probably to its low solubility and consequent poor absorption from the alimentary tract Its sodium salt differs from the sodium salts of sulphathiazole and sulphapyridine in not yielding a highly alkaline solution Sodium sulphacetamide is issued as Albucid soluble or Sulphacetamide soluble It is employed intramuscularly and as a 30% solution for intravenous injection, and a 2 5% solution has been advocated for application to the eyes in the prophylaxis of bacterial infection following injury by vesicant war gases Albucid and albucid soluble have been placed on the market in Canada under the names Sulamyd and Sulamyd soluble Sulphacetamide differs from the acetyl derivative of sulphanilamide, into which the latter is partly converted in the body, since in sulphacetamide it is a hydrogen of the amide group which is replaced by the acetyl radical, whereas with acetyl sulphanilamide substitution takes place in the amino group Analogous conjugation takes place with sulphapyridine, sulphathiazole, sulphadiazine and a number of other sulphonamide drugs Unlike these compounds sulphacetamide appears to be partly broken down in the body to sulphanilamide

Sulphacetamide

Acetyl sulphanilamide

CHEMOTHERAPY INSIDE THE BOWEL

The absorption of a sulphonamide from the alimentary tract or from a wound chiefly depends on its solubility in water at body temperature Thus the solubility and absorbability of sulphanilamide, sulphathiazole and sulphapyridine decrease in that order Other factors, however, have an influence on degree and rate of absorption and some compounds, much more soluble than sulphapyridine or sulphathiazole, have a low degree of gastro-intestinal absorption The idea arose, therefore, of using a sulphonamide which is bacteriostatically active, fairly water-soluble and of low absorbability to combat infections which are largely confined to the alimentary canal Marshall, Bratton, White and Litchfield (1940), who studied various compounds from this point of view, found that sodium sulphanilyl sulphanilate, N^1-(2-hydroxyethyl) sulphapyridine, N^1-diglycosulphapyridine and sulphanilylguanidine fulfilled the requirements of water-solubility and limited absorption from the intestine Since sulphanilylguanidine appeared to be the most active of these compounds against a number of pathogens it was selected for pharmacological and therapeutic investigation (It may be recalled that sodium sulphanilyl sulphanilate once achieved a short-lived but world-wide interest for a supposed activity in virus infections) Sulphanilylguanidine is p-amino-N-guanylbenzenesulphonamide Marshall and his colleagues suggest that the formulæ may both be considered correct for the compound as they are probably resonance isomers, easily transformed one into the other



α sulphanilylguanidine   β sulphanilylguanidine

Sulphaguanidine

The blood levels reached after the administration of sulphanilylguanidine are low as a consequence of its limited absorption, and the concentration in the gastro-intestinal tract is correspondingly high. It is suggested for trial in bacterial infections which are chiefly localised in the intestines, such as bacillary dysentery, cholera and the early stages of the enteric fevers, and for reducing the hazards of intestinal surgery In acute bacillary dysentery it will have to be established that sulphanilylguanidine has advantages over sulphathiazole and sulphapyridine, those " veritable Excaliburs, with which dysentery apparently may be vanquished without fail "

(Ravenel and Smith (1941)) Other sulphonamides have proved inactive on *Vibrion choleræ* at ordinary therapeutic concentrations but Marshall and others have found sulphanilylguanidine bactericidal in vitro in a concentration of 200 mg per 100 c cm , so that at the high levels reached in the gastro-intestinal tract it is possible that the administration of this compound may be of benefit in cholera Its use in intestinal infections bears some analogy with the use of sulphonamides in infections of the urinary tract, where the concentration in the urine is, of course, enormously greater than in the blood and tissues

Various sulphonamides have given unquestionable benefit in cases of ulcerative colitis, although the mechanism of the effect must necessarily remain obscure while the ætiology of this condition is unknown, and a few experiences in the use of sulphanilylguanidine in ulcerative colitis are encouraging The drug is being known as sulphaguanidine, by analogy with sulphapyridine and sulphathiazole

OTHER SULPHUR COMPOUNDS

Not all the sulphur compounds which are active antibacterial agents are sulphonamides , a number are sulphones, sulphoxides and sulphides The sulphones (table II), which have been investigated experimentally as well as clinically, may be regarded as derivatives of 4 4′-diaminodiphenylsulphone This substance has proved excessively toxic to mice but not to some other laboratory animals, and its toxicity probably precludes its clinical employment in man McEwen, Pizer and Paterson (1941) have reported the rather unexpected finding that the compound is of relatively low toxicity for cattle, producing no toxic effects in therapeutic doses The di-acetyl derivative of 4 4′-diamino-diphenylsulphone is of low toxicity and has been used in France for the treatment of gonorrhœa under the proprietary name Rodilone (1399 F) The glucoside of 4 4′-diamino-diphenylsulphone has been studied for its activity in experimental bacterial and virus infections, and has been used clinically in the treatment of cerebrospinal fever, trachoma and lymphogranuloma inguinale A compound known as Promin and described as the sodium salt of *p p′*-diamino-diphenyl-sulphone-N,-N^1-di-dextrose sulphonate has been tried in artificially induced animal infections with various coccal and bacillary organisms, and used clinically by mouth and intravenously This drug has been found to possess a retarding influence in experimental tuberculous infections of guineapigs apparently greater than that conferred by sulphonamides At present, however, the effective chemotherapy of clinical tuberculous infections remains, with that of brucellosis, and the introduction of virucidal agents, probable achievements of the future Despite the number of compounds in clinical use and the far greater number which have been studied experimentally, the tremendous strides made during the past few years constitute but the beginning, howbeit a highly successful one, of a new era in therapeutics

Two footnotes from "The New Chemotherapy in Puerperal Infections," by G F Gibberd (*Guy's Hosp Gaz* Nov 15, 1941, p 290)

Note for those who think that curative medicine began with the discovery of sulphanilamide N B —Prior to 1936 more than half of the patients suffering from hæmolytic streptococcal septicæmia in the puerperium did, in fact, recover

Note for those who believe in the maxim "when in doubt give sulphanilamide" N B —One of the deaths in the 1936–39 group occurred in a patient whose infection was proved at post-mortem examination to have been confined entirely to the birth canal She died from agranulocytosis, not from hæmolytic streptococcal infection She died from sulphanilamide She died from treatment

---

ACTIVE IMMUNISATION AGAINST TETA

D G EVANS, PH D MANC

(*National Institute for Medical Research*)

Ramon and Zoeller (1927) originally advocated the use of tetanus toxoid for the active immunisation of man against tetanus infection, and since then immunisation has been practised extensively in many countries, especially since the outbreak of the present war The type of antigen to be used, the dose to be administered the number of doses to be given and the interval between the doses have been the subject of much discussion and research The methods by which active immunisation with toxoid is effected vary in different countries On the Continent it is usual to administer three doses of toxoid at relatively short intervals, but Boyd (193 showed that equally good results were obtained by giving two doses, each of 1 c cm at an interval of not less than 6 weeks, and this practice is followed in England, Canada and several other countries Boyd pointed out that 6 weeks may not be the optimum interval and suggested that wider spacing of the doses might achieve better results His main observations have been confirmed by many workers, and Marvell and Parish (1940) have shown that when the doses are injected at an interval greater than 6 weeks a larger quantity of antitoxin is produced Maclean and Holt (1940) have recently shown that a good response follows the injection of two doses of toxoid given at an interval of 4 weeks, and that when the toxoid is combined with T A B vaccine the response, as judged by the antitoxin formed, is even better They consider that it is unnecessary to prolong the interval from 4 to 6 weeks when the toxoid is combined with T A B vaccine From the administrative point of view there appears to be an advantage in employing two rather than three doses and there is a large amount of evidence and experience in support of the efficacy of two widely spaced doses On the other hand, the administration of three doses of toxoid, each of 1 c cm , at an interval of 3 weeks between the doses i recommended for the immunisation of the military personnel of the United States of America (*Bain 1941*)

The procedure finally adopted will, no doubt, be based on the results of trials made in different ways In July, 1940, active immunisation was offered to members of the staff of the National Institute for Medical Research, Hampstead The method of immunisation was similar to that of Boyd, but the opportunity was taken (*a*) of investigating the effect of increasing the interval between the doses of toxoid to 9 weeks, (*b*) of determining the antitoxin content after a single injection of toxoid, as well as 4 and 10 months after the second injection, and (*c*) of investigating the effect of giving a third dose of toxoid 10 months after the second dose

IMMUNISATION WITH TWO DOSES OF TOXOID

Two doses of tetanus toxoid each of 1 c cm were injected at an interval of 9 weeks into 81 subjects The toxoid was given subcutaneously into the left arm and blood samples taken on three occasions (1) immediately before the first injection, (2) immediately before the second injection, and (3) 17 weeks after the second injection A small group of 16 persons were bled for a fourth time 10 months after the second injection The sera were tested for tetanus antitoxin and the result are given in table I

Of the 81 sera tested before inoculation, no sample showed as much as 0 01 international unit per c cm Nine weeks after the first injection, 22 of the 53 person whose sera were tested still had less than 0 01 unit of antitoxin, while the remainder had developed more than 0 01 unit and almost a fifth of the persons more than 0 1 unit

These results suggest that some persons had some basal immunity, a condition which may exist without evidence for it always being shown by the presence of detectable amounts of circulating antitoxin Even if a person has not developed any basal immunity previously, this is very effectively provided by the first injection of toxoid, since after the second injection all the 70 persons tested had developed more than 0 01 unit, all but 2 showed more than 0 02 unit and as many as 59 more than 0 1 unit. It is to be noted that the values were recorded 17 weeks after the second injection indicating that a high and what is usually regarded as adequate, concentration of antitoxin had been maintained during this period Moreover, the examination of the sera of 16 persons 10 months after the second injection showed that the level of the antitoxin had been substantially maintained Comparing the values in table II at 4 and 10 months after the second injection it is seen that while those persons who had developed more than 1 unit of antitoxin showed some reduction in titre, in 9 of the cases the antitoxin content of the serum had remained unchanged

TABLE I—TETANUS ANTITOXIN TITRES OF SERA FROM PERSONS BEFORE AND AFTER INOCULATION WITH TETANUS TOXOID

Blood sample taken	No of samples	No of sera showing titre (I U per c.cm) of					
		less than 0 01	more than 0 01	more than 0 02	more than 0 1	more than 1	more than 5
Before first inoculation	81	81	0	0	0	0	0
9 weeks after first inoculation	53	22	31	22	10	0	0
17 weeks after second inoculation	70	0	70	68	59	19	0
10 months after second inoculation	16	0	16	16	14	0	0

It may be mentioned that 39 of the 81 subjects received in the interval between the injections of the two doses of toxoid, two doses of T A.B vaccine, and 12 of these 39 also received an injection of influenza virus A vaccine within the same period It cannot be assumed that these additional injections of other antigens were entirely without effect on the production of tetanus antitoxin, but the conclusion may safely be drawn that they did not interfere with the active immunisation against tetanus

EFFECT OF A THIRD DOSE

It is the practice in certain countries, particularly in the armed forces, to give a further injection of tetanus toxoid a year after the first immunisation has been completed (Ramon 1939 Bain 1940) In this series, the opportunity occurred of investigating the effect of a third injection of toxoid on the antitoxin content of 16 of the persons who had been successfully immunised by two injections 10 months previously The effect of the third injection was studied by determining the antitoxin content (1) immediately before, (2) 5 days, (3) 12 days and (4) 30 days after the third inoculation

TABLE II—TETANUS ANTITOXIN TITRES OF SERA FROM 16 PERSONS BEFORE AND AFTER A THIRD INOCULATION OF TETANUS TOXOID

No of serum	Antitoxin titre (I U per c cm)				
	After 2nd inoculation		After 3rd inoculation		
	4 months	10 months	5 days	12 days	30 days
1	0 02–0 1	0 02–0 1	0 02–0 1	2–5	2–5
27	0 1–1	0 1–1	2–5	10–20	10–20
31	0 02–0 1	0 02–0 1	0 1–1	2–5	2–5
35	0 1–1	0 1–1	1–2	10–20	5–10
40	1–2	0 1–1	2–5	20–50	20–50
44	1–2	0 1–1	2–5	20–50	20–50
48	1–2	0 1–1	5–10	20–50	20–50
52	1–2	0 1–1	2–5	20–50	20–50
58	0 1–1	0 1–1	1–2	10–20	5–10
59	1–2	0 1–1	10–20	20–50	20–50
64	0 1–1	0 1–1	5–10	20–50	20–50
65	0 1–1	0 1–1	2–5	20–50	10–20
66	0 1–1	0 1–1	2–5	10–20	5–10
68	1–2	0 1–1	2–5	10–20	10–20
93	1–2	0 1–1	2–5	20–50	10–20
105	0 1–1	0 1–1	1–2	5–10	2–5

The results of these tests are given in tables II and III, and the values found 6 months earlier (that is 4 months after the second injection) are also included

The response to the third injection, given 10 months after the second injection was well marked In every case but one there was an increase in the antitoxin produced 5 days after the injection, and this increase continued to the 12th day, when 8 samples contained more than twenty units, 5 more than ten units, 1 more than five units and 2 more than two units This large increase was maintained, unchanged in 10 cases, for 30 days

DISCUSSION

The concentration of antitoxin in the circulating blood necessary to afford protection against tetanus is not precisely known It may be that, as in the case of diphtheria, the actual concentration of antitoxin at the time of infection is not the sole factor in determining whether tetanus will develop when an actively immunised person is exposed to infection The responsiveness of the immunising mechanism established by the injection of toxoid is considered by many authorities to be a factor of possibly equal importance However, from the experience gained in the last war, there are good grounds for believing that a concentration of antitoxin of as little as 0 01 unit per c cm is adequate for preventing the onset of tetanus in wounded persons, and if this is so the results show, in agreement with those of others, that this concentration is produced and maintained for many months in persons who have received two spaced injections of toxoid

The results also suggest a point which may be of practical administrative importance Boyd showed that the interval between the two doses should not be less than 6 weeks and these experiments have shown that the interval may be extended to 9 weeks To extend the interval may sometimes be convenient, but in any case it is clear that the second dose may be deferred for several weeks at least without endangering the efficacy of the active immunisation

TABLE III—SUMMARY OF FINDINGS IN TABLE II

Blood sample taken	No of sera showing titre (I U per c cm) of						
	0 02–0 1	0 1–1	1–2	2–5	5–10	10–20	20–50
4 months after second inoculation	2	7	7	0	0	0	0
10 months after second inoculation	2	14	0	0	0	0	0
5 days after third inoculation	1	1	3	8	2	1	0
12 days after third inoculation	0	0	0	2	1	5	8
30 days after third inoculation	0	0	0	3	3	4	6

A striking feature of a further injection of toxoid into actively immunised persons is the rapidity with which antitoxin is produced There seems to be no record of the effect produced by absorption of the toxin in an actively immunised person infected with tetanus organisms, but, in so far as such a condition may be regarded as providing a secondary stimulus to the established immunising mechanism, these results suggest that the actively immunised person is provided in his capacity to produce antitoxin rapidly in response to a specific stimulus, with an additional safeguard against the onset of tetanus The administration of a further injection of toxoid a year or more after the first immunisation has much to recommend it Although tetanus toxoid is remarkably certain in its action there are as judged by the antitoxin produced some persons who respond better than others and it is possible that in a larger series there might be some cases in which immunisation had apparently failed In the case of tetanus there is, as yet, no simply applied test like the Schick test in diphtheria, by which these failures can be discovered If the procedure of giving a third injection after a year were generally applied those persons who did not become effectively immunised by the two earlier injections as well as those in whom the antitoxin level had fallen would be more certainly provided for, and the chance of an actively immunised person developing tetanus which recent experience suggests to be very small (Perry 1940), would be still further reduced The question whether the extra protection thus afforded would be offset by the additional trouble is one for administrative decision

In view of the fact that actively immunised persons respond rapidly to a third injection by the production of antitoxin in large amounts, it has been suggested that persons wounded many months after immunisation need only be given toxoid and not antitoxin Recent advocates of such a procedure are Kestermann and Vogt (1940), and the U S War Department, in recently issued instructions governing the administration of tetanus toxoid and antitoxin to military personnel (Bain 1941), state that wounded persons who have been immunised are to be given tetanus toxoid, and those who have not been immunised are to be given antitoxin There is, however, not sufficient evidence to support an assumption that the same dramatic increase in antitoxin would necessarily occur in persons in whom infection by other organisms had become established, or, as pointed out by Marvell and Parish (1940), in seriously wounded persons suffering from shock

SUMMARY

Examination of the sera of 81 persons (age 15–60 years), before active immunisation against tetanus, showed that none contained as much as 0 01 international unit of tetanus antitoxin per c cm

Nine weeks after the first injection of tetanus toxoid, examination of the sera of 53 persons showed that in 31 cases the antitoxin content was more than 0 01 unit, but that 22 still contained less than 0 01 unit

Seventeen weeks after the second injection of toxoid, given nine weeks after the first, all the 70 persons examined had more than 0 01 unit, 68 more than 0 02 unit, 59 more than 0 1 unit and 19 more than 1 unit

The antitoxin level was substantially maintained for ten months after the second injection

The administration of a third dose of tetanus toxoid ten months after the second injection to 16 of these persons was followed by a large and rapid increase in the antitoxin content of the serum, and the high level was maintained substantially unchanged for a month

PLACENTAL BLOOD IN THE TREATMENT OF AMENORRHŒA

J Halbrecht, M D

DEPARTMENT OF GYNÆCOLOGY, BEILINSON HOSPITAL, PETAH TIQVA, PALESTINE

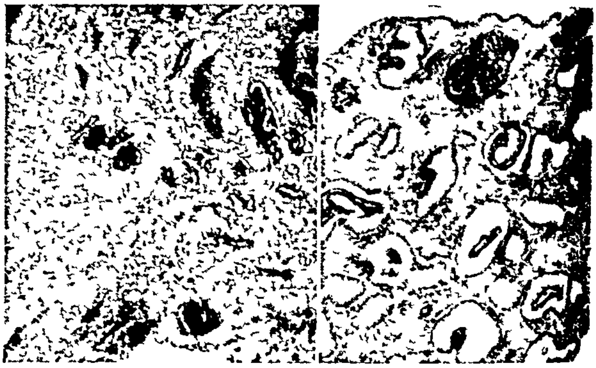
THE treatment of amenorrhœa and sterility with various gonadotropic hormones has been unsatisfactory up to now, owing to the fact that these hormones, though showing some effect on the ovaries of rodents, have none on the ovaries of women and monkeys Recently positive results have been reported from the use of the serum of pregnant mares, but it is too early to give a conclusive verdict on its value

It seems possible that gonadotropic preparations might fail because they contain an incomplete hormonal complex they lack an activator which is present in the blood This would explain the better results obtained with the serum of pregnant mares I therefore decided to investigate the effect of placental blood Vaginal bleeding and lactation in the newborn seem to indicate that placental blood is rich in hormones, though no exact laboratory estimate has yet been made of its hormonal content If correctly obtained it causes no graver reactions than ordinary blood, and by using plasma I eliminated the danger of hæmolytic crises

In order to determine whether placental blood really was active I gave injections of it to 34 amenorrhœic women, with the result that 18 menstruated within 5–35 days after the end of the course of treatment, in most of them menstruation began between the 15th and the 20th days A further 3 patients menstruated on or after the 35th day Of those I was able to follow up, 5 menstruated once only, 8 twice or more, the others were not traced In the light of subsequent experience it seems likely that those who failed to menstruate may have received too little blood At first I gave only three or four injections of blood A few patients menstruated after receiving small q —a few drops—but others required larger amounts

In 11 cases the effect of placental blood, or plasma, on the uterine mucosa was determined by histological examination before and after treatment

Method—Before treatment I dilated the cervix up to Hegar 5–6, curetted lightly with the finest curette, and examined the endometrium histologically Treatment by placental blood or plasma was begun immediately afterwards Each patient received 5–6 injections of 150–200 c cm—in some cases all plasma, in others at least half plasma—given intravenously Treatment was ambulatory and the patient received a total of 800–1000 c cm Sometimes they developed fever, but as a rule there was no reaction of this kind After every injection the patient was given Pyramidon, 0 3 g, which I think prevents the milder reactions The intervals between injections depended on how the patient felt, but I usually gave one every second day



(a) (b)

Patient aged 29 years with amenorrhœa for 10 months (a) Endometrium before treatment, completely atrophic (b) Endometrium 14 days after treatment, showing normal appearance

Curettage before treatment produced more or less atrophic endometrium After 3 injections of placental blood of 150 c cm each, and 3 injections of plasma in similar dosage, 5 patients showed a complete change in the endometrial structure from atrophy to the proliferative or secretory state All 5 menstruated shortly after treatment, though they had been amenorrhœic for periods ranging from 5 months to 2 years Another patient menstruated 20 days after the beginning of treatment but the mucosa remained atrophic The remaining 5 patients did not react at all, one had not menstruated for 15 years and examination of the uterine mucosa showed tuberculous endometritis I had removed the one remaining ovary of another woman a year before She had developed menopausal symptoms which were not affected by placental blood, and no change was seen in the uterine mucosa This case suggests that the action of placental blood does not depend on its folliculin content but on gonadotropic substances present in it The remaining 3 unresponsive cases had not menstruated for periods ranging from 2 to 5 years, and were suffering from climacterium præcox In all cases which menstruated or showed changes in the endometrium the size of the uterine cavity increased from 1 to 2 5 cm

SUMMARY

A series of 34 patients who had had amenorrhœa fo periods ranging from 4 months to 15 years received placental blood or plasma intravenously, 18 of them menstruated within 5–35 days of the end of treatment

Of 11 patients showing atrophy of the endometrium before treatment, 6 had a normal endometrium after 5-6 intravenous injections of 150–200 c cm of placental blood or plasma

These results indicate that placental blood is rich in gonadotropic substances

(Divisions of Medicine and Pathology, No. 15 Canadian General Hospital, R.C.A.M.C.)

SINCE the identification of the meningococcus by Weichselbaum in 1887, the clinical concept of meningococcal infection has been dominated by its most serious manifestation—meningitis. As early as 1899 Gwyn recovered meningococci from the blood of patients suffering from meningococcal meningitis and in 1902 Salomon described meningococcal septicæmia without meningitis. Although of recent years reports (Applebaum 1937, Heinle 1939, Stott and Copeman 1940) of similar cases of meningococcal blood-stream infection have become more numerous the disease is still regarded by most physicians as a clinical rarity.

A series of 26 patients suffering from meningococcal infection were admitted to No. 15 Canadian General Hospital in the period July 1940, to June 1941, inclusive. Of these 11 did not have meningitis on admission (though one, case 10, subsequently developed it) but had meningococcal septicæmia. We thus had an opportunity to observe the course of infection in these patients and to compare their histories with those of meningitic cases seen in the same body of troops at the same time. The cases were sporadic, occurring in every month of the year. They came from Canadian troops stationed in England, but were not otherwise related to each other or to other recognised cases of meningococcal infection. For presentation the series is divided into two groups: an amenimgitic and a meningitic.

THE AMENINGITIC GROUP

The 11 patients without meningitis came to hospital under a variety of diagnoses including influenza, arthritis, erythema nodosum and rheumatism. The diagnosis in 10 of the 11 cases was proven by growing *Neisseria meningitidis* from the patient's blood (table I). The clinical manifestations, however, were such as to render a diagnosis possible in most cases.

The onset was sufficiently definite to enable the patient to fix its date with fair precision. Thereafter the course was marked by striking remissions, varying greatly in length, and by even more striking relapses. The early symptoms of fatigue, malaise, feverishness, chilliness, occasional true rigor, aching pains in the limbs and back, and sometimes moderate intermittent headache, were those which characterise the onset of many acute infections. Other symptoms and signs of more particular diagnostic value were superimposed on this general picture of infection. These were localised muscle pain, localised joint pain and skin lesions.

The localised muscle pain, present in 10 of the 11 patients, differed sharply from the aching pain common in acute infection. Its onset was abrupt, associated with fever and general symptoms of infection, and often with localised joint pains and with crops of the skin lesions described below. While in some it was little more than stiffness, it was of sufficient severity to form the chief complaint of 5 of the patients. It was increased by movement. Its site could be localised accurately by the patient and was tender. The calf muscles were most commonly affected, less often those of the back, thighs and arms.

Localised joint pain, aggravated by movement, occurred in 8 of the patients and was a chief complaint in 3. Its onset too, was abrupt and associated with symptoms of infection and frequently with a crop of skin lesions. In 3 cases the pain was associated with redness, swelling and increased heat: in 1 of these there was increased joint fluid. These 3 patients came to hospital with a diagnosis of arthritis. In some patients the joint pain seemed to be related to a tender skin lesion overlying the joint, while in others it was not associated with any demonstrable abnormality. The pain usually disappeared in a few days, only to recur in the same or in other joints. One or more joints were involved at one time, more commonly the large joints, but sometimes the small joints of the hands and feet.

Skin lesions appeared at some time during their illness in all the patients except one, case 8, whose illness was only of two days' duration before treatment. The spots appeared suddenly, in crops of a few or dozens, at any place on the body surface, but most commonly on the limbs and trunk. Their occurrence coincided with or closely followed the onset or recurrence of fever and general symptoms of infection. The patient's attention was drawn to them not only by their appearance but also because many were painful and tender. The spots varied in colour, size, palpability and tenderness. Most of them were clearly demarcated bright pink circular areas, 5–35 mm. in diameter, the smaller sizes predominating. They were regular in outline; some had a central dark purplish red spot or streak, and a few of the larger spots were darker and resembled somewhat the lesions of erythema nodosum. On pressure the pink zones faded, but the purplish red centres persisted, indicating hæmorrhage. Most of the larger lesions and all those with hæmorrhagic centres, were palpable. Some were elevated slightly above the skin surface, others were deeper. Many of the lesions, particularly the larger ones, were moderately painful and tender. Often such spots marked the site of localised muscle or joint pain. Subsequent examination revealed changes in the lesions. After a few hours or next day, some which had appeared at first as red macules had developed hæmorrhagic centres and become palpable. In two to four days the redness faded and the tenderness disappeared. Slight staining from the central hæmorrhage and sometimes a small lump, persisted for a week or more. The lesions were in no way similar to the blotchy purpuric eruption commonly observed in cases of cerebrospinal fever and occurring in some of the meningitic cases in this series (table II).

The appearance of a crop, or crops, of the skin lesions, associated with fever, general symptoms of infection and localised muscle and joint pain, usually accompanied by leucocytosis, provided a clinical picture which strongly suggested meningococcal septicæmia.

Enlargement of the spleen was not observed in any of the cases. The only evidence of endocarditis found was that of a pre-existing aortic insufficiency due to rheumatic fever in childhood in case 8. No change in the character of the murmur was observed during his stay in hospital, and the course of the disease in this patient did not differ from the others. Under treatment he made a complete recovery from the meningococcal infection.

The cerebrospinal fluid was examined in 6 of the 11 cases, although none presented any clinical evidence of meningitis. In all the fluid was normal in cell and protein content and was sterile on culture.

In this group, 9 patients were treated with sulphapyridine during the ameningitic phase; 8 made a complete recovery after the administration of 34 g. of the drug in seven days, 12 g. being given in the first twenty-four hours. In case 3 the diagnosis was not made, and consequently treatment was not instituted until the disease had been present for three months. Although the infection was then cured by chemotherapy and did not recur this soldier was left with residual joint pain, which necessitated lowering his medical category. Case 1 was not given chemotherapy and case 10 was not given sulphapyridine until meningitis developed. The case-histories of these 2 patients well illustrate features presented by most of the patients in the group. They also show certain features of special interest and serve to stress the importance of recognition and treatment of meningococcal septicæmia.

CASE 1.—A gunner, aged 39. He had been well until May 23, when he had developed malaise, chilliness, feverishness and aching pain in the back and limbs. He was evacuated to a military hospital. Temperature was 103° F., leucocyte count 17,000 with 77% neutrophils. Meningitis was suspected, but the C.S.F. was normal and sterile on culture. On May 25 he developed pain in the knees, ankles and shoulders. He was transferred to an E.M.S. hospital and treated for rheumatism during the next five weeks. During this time he noted repeated crops of spots in the skin, many of them tender, appearing in association with recrudescence of fever, muscle pain and joint pain. On July 6 he was admitted to this hospital. At that time the right knee and ankle were painful and swollen, movement was restricted by pain Many red, palpable, tender spots about the size of a sixpence were scattered over the limbs and trunk Some of these had hæmorrhagic centres From July 6 to 28 he had repeated remissions and relapses Thereafter he remained free of symptoms and was sent to a convalescent depot on Aug 12 A diagnosis of arthritis was recorded

In retrospect it appears certain that this patient suffered from meningococcal septicæmia, and that the diagnosis was missed both by ourselves and at the two other hospitals The two blood samples taken while in this hospital did not show any growth, but such evidence is quite inadequate (see table I) to exclude the diagnosis of meningococcal septicæmia in a patient presenting the above clinical findings This patient was still free from recurrence about three months later, having made, apparently, a spontaneous recovery, but he was invalided home to Canada on account of residual joint pain

TABLE I—THE AMENINGITIC GROUP

Case	Admitted	Duration (days)	Muscle pain	Joint pain	Skin lesions	Leucocyte count	No of blood samples	Positive
1	July 6, 1940	45	+	+	+	17,000	2	0
3	July 31	90	+	+	+	18,000	2	1
6	Aug 30	17	+	−	+	18,000	1	1
8	Oct 25	2	−	−	−	23,000	1	1
10	Nov 23	12	+	+	+	11,000	2	1
12	Jan 1, 1941	60	+	+	+	9000	4	2
15	Feb 18	15	+	+	+	14,000	10	4
17	Feb 25	27	+	+	+	10,000	4	1
20	March 15	7	+	+	+	22,000	6	4
21	March 24	28	+	+	+	17,000	21	2
26	June 14	33	+	+	+	10,000	14	12

CASE 10 —A sapper, aged 19 He had been in good health until Nov 16, 1940, when he became suddenly ill with fatigue, malaise, feverishness, chilliness, headache and localised pain in the right calf He felt better for the next two days, during which he remained on duty On Nov 19 he became more ill, temperature 104° F, a crop of red tender spots appeared in the skin, he was evacuated to a dressing station where he again had a short remission On the 21st he had recurrence of fever and more spots, and on the 23rd, when there was fever again and more spots, he was transferred to this hospital Temperature 103° F, many skin lesions present, some tender and many palpable with hæmorrhagic centres Leucocyte count 11,000 with 88% neutrophils Next day his temperature was normal and the spots fading On the 25th he had a rigor, temperature rose to 104 6° F He complained of malaise, moderate headache and general aching pain with more severe and localised pain in the left elbow There were many new skin lesions, one of which, very tender, was situated over the left elbow Lumbar puncture revealed clear fluid under normal pressure, 3 lymphocytes per c mm, Pandy test negative, fluid sterile A blood sample taken on this day yielded *N meningitidis* group I on Nov 28 By this time, however, the patient was afebrile and symptom-free No specific treatment was instituted He felt well and was up and about the ward until Dec 16 (18 days intermission) On that day he again had a rigor and his temperature rose to 103° F He complained of *malaise and aching pains in limbs and back A new crop of* spots appeared He developed headache, which rapidly became severe, slight neck pain and stiffness Blood taken at this time was sterile C S F 100 neutrophils per c mm, protein 40 mg per 100 c cm, no organisms seen on direct smear, but culture yielded *N meningitidis* group I Under treatment with sulphapyridine the patient made a complete recovery, although the C S F cell count rose to 1200 during the first 12 hours of treatment

This case was thus observed first in the ameningitic phase of the disease Then, after a period of freedom from symptoms, the infection again became manifest, but this time meningitis developed The case serves to stress the close association between the type of meningococcal infection and the meningitic a relationship that is further demonstrated on [illegible] tion of the meningitic group

THE MENINGITIC GROUP

The clinical histories of the patients comprising this group indicated the presence of infection for periods varying from a few hours to several weeks before the onset of meningitis While it is impossible to identify precisely the beginning of meningeal inflammation, there are grounds for assuming that it approximates in time to the onset of severe persistent headache Although such headache was the chief complaint of all the patients who were conscious at the time of admission, in no case was it the first symptom of the illness That headache of this type may accompany very early meningeal involvement is apparent from case 10, where lumbar puncture was done within four hours of the onset of persistent headache, the Pandy test was negative, the C S F cell count was only 100 neutrophils, and culture yielded N *meningitidis* group I The premeningitic period shown in table II refers therefore to the time between the onset of symptoms and signs of infection, and the onset of severe persistent headache This premeningitic period lasted from one to seven weeks in 5 cases, from one to six days in 4 cases, and from three to sixteen hours in 6 cases In one case the information was not recorded The early symptoms were, as in the ameningitic group, those commonly characteristic of the onset of acute infection However, in an appreciable number of the patients there were additional features which indicated a more specific diagnosis

In 8 of the 9 cases in which the premeningitic period lasted longer than one day, the signs and symptoms occurring in this phase of the disease were clearly defined These 8 patients gave a history of localised joint pain, associated with localised muscle pain in 6, and with skin lesions of the type described above in 5 Further, all 5 patients in whom this period exceeded a week gave a *history of remissions and relapses* In short, the illness of these patients before the onset of meningitis was essentially similar to those of the patients in the ameningitic group In 3 of the 6 cases in which the premeningitic period was less than one day the symptoms were essentially similar to those of the ameningitic group —muscle pain, joint or skin lesions either singly or in combination In 2 cases the information was not

TABLE II—THE MENINGITIC GROUP

Case	Admitted	Duration of ameningitic phase	Muscle pain	Joint pain	Skin lesions	Purpura	Leucocyte count	Blood culture	C S F			Duration of meningitis before treatment (hr)
									Cells	Film	Culture	
2	1940 July 17	?	?	?	−	−			1200	−		12
4	Sept 11	3 hr	?	?	−	−	31,000	+	3600	+	+	12
5	Sept 29	16 hr	−	+	−	+	23,000	+	40,000	+	+	36
7	Oct 24	15 days	+	+	−	−	14,000	−	2500	−	+	10
9	Nov 7	4 days	−	−	−	−	17,000	−	20,000	+	+	24
10	Nov 23	30 days	+	+	+	−	12,000	−	100	−	+	5
11	Dec 10	6 days	?	+	−	−	18,000	−	12,000	−	+	24
13	1941 Jan 2	30 hr	−	+	−	−	19,000	−	6500	+	+	36
14	Jan 13	6 hr	−	−	−	+	17,000	−	16,000	−	−	1
16	Feb 21	12 hr	−	−	+	+	26 000	−	37,000	+	+	1
18	Feb 27	3 hr	−	−	+	−	24 000	+	9000	+	+	48
19	Mar 11	11 days	+	+	+	−	14,000	−	6500	−	−	4
22	April 2	12 hr	−	+	−	+	20,000	+	250	−	+	[illegible]
23	April 8	2 days	+	+	+	−	22,000	−	9000	+	+	12
24	April 30	14 days	+	+	+	−	16,000	−	9000	+	+	10
25	May 7	49 days	+	+	+	−	10 000	−	1200	−	+	24

obtained. In case 14 it is known that such signs or symptoms were not present although the patient was ill with general symptoms of infection for six hours before the appearance of any headache. The clinical records of some of the patients are even more enlightening than the tabulated data. For example in case 5 the soldier first reported to his regimental medical officer because of pain in the right ankle and knee, and was evacuated to a casualty clearing station with a diagnosis of rheumatism. In case 22 the patient complained of sudden severe pain in the right shoulder approximating in time to the onset of the headache. It should be pointed out here that the patients suffering from meningitis seldom gave this history at the time of admission to hospital. The more distressing symptoms of meningitis tended to obliterate the memory of the milder symptoms of the *earlier illness*. However, with the disappearance, under treatment, of the headache, irritability and mental confusion the patients recalled their preceding illness vividly.

It is apparent from table II that the cases varied greatly in severity from mild to fulminating. Meningococci were recovered from the cerebrospinal fluid in 13 of the 16 cases. In 1 the fluid was not cultured, in 2 it failed to yield any growth. These 3 were clinically typical cases of cerebrospinal fever. The intervals between the onset of meningitis and the beginning of treatment were from five to seventy-two hours.

In addition to the usual symptomatic treatment, sulphapyridine was used as in the ameningitic cases, but was continued for ten days and a total of 40 g. was given. In all but the mildest cases the dosage by mouth was augmented by the intravenous administration of 2–4 g. of sodium sulphapyridine at the onset of treatment. Unconsciousness or persistent severe vomiting made necessary the continuation of the intravenous therapy in cases 5, 14 and 22. Blood levels of 4.2–12 mg. of free sulphapyridine per 100 c.cm. and C.S.F. levels of 2.7–10 mg. per 100 c.cm. were obtained during the first forty-eight hours.

Of the 16 patients, 12 made a rapid and complete recovery, all symptoms disappearing in three to five days. In these the C.S.F. pressure, cell-count and protein content fell rapidly, but in some several weeks passed before the cell-count and protein were entirely normal. Deafness, present in 3 patients on admission, cleared entirely in 2; the third was left with slight nerve deafness not sufficient to lower his medical category. This patient had mild intermittent headache which persisted for ten weeks. One patient continued to complain of slight headache and neck pain for eight weeks; in this case, although the cell-count and protein content returned rapidly to normal the C.S.F. pressure continued high; the end-result is not yet known. Cases 5 and 22 died.

Case 5, a fulminating infection with severe meningitis, was comatose on admission and the cell count in the spinal fluid was 40,000; *N. meningitidis* was recovered from both blood and C.S.F. The patient showed some improvement and subsequent samples of blood and C.S.F. failed to yield growth. In spite of this temporary improvement, the coma deepened, breathing became rapid, stertorous and irregular, pulse and temperature rose. Clinically death occurred from respiratory failure. At necropsy there was much œdema of brain and spinal cord with flattening of the cerebral convolutions, and the brain was compressed downwards with herniation of the hippocampal unci through the tentorial notch, and of the cerebellar tonsils through the foramen magnum. This cerebellar pressure cone was well developed. The pial blood-vessels were intensely injected, but practically no meningeal exudate was present. Death was apparently due to medullary compression consequent on increased intracranial pressure.

Case 22 was desperately ill on admission, with extensive purpura and showed only 250 cells in the C.S.F.; this, however, yielded meningococci, as did the blood. With treatment there was temporary clinical improvement and both blood and C.S.F. became *sterile*. The early improvement was followed by acute left heart-failure, manifested by acute pulmonary œdema and rising pulse rate. He died thirty six hours after admission. At necropsy, although the pial vessels were extremely injected and the brain somewhat œdematous, there was a complete absence of gross meningeal exudate, and microscopically several sections had to be studied before evidence of scanty cellular exudate was seen. Generalised purpuric hæmorrhages and an extremely flabby heart, the chambers of which were much dilated, were indications of the severe toxæmia.

BACTERIOLOGY

Blood samples were planted in glucose broth. C.S.F. was drawn directly at the bedside into small vials containing sloped Löffler's medium. It is evident (tables I and II) that recovery of the organism from the blood in non-fulminating cases was largely a matter of chance. For example, twenty-one samples of blood from case 21 yielded only two positive cultures. Growth was demonstrable in some cultures in twenty-four hours, but in others longer periods of incubation up to ten days were required. This variation was found in cultures obtained at different times from the same patient. For instance, one blood sample from case 26 yielded growth in twenty-four hours; another required seven days before growth was demonstrable by film or subculture.

All the strains isolated gave typical fermentation of glucose and of maltose. They were tested for agglutination with specific antisera by the late Dr. W. M. Scott and Dr. Marion Watson, from whose reports the following summary is made:

Of the 10 strains isolated from the ameningitic group cases 6 and 26 were group I; cases 12 and 20 were group I, type III; case 10 was group I, uncommon type; case 15 was group I, aberrant type; case 17 was probably group II; case 8 was agglutinated by group I and group II antisera; cases 3 and 31 were not agglutinated by either. So far as the agglutinative type was concerned, therefore, the strains exhibited considerable variety. Of 10 of the strains isolated from the meningitis cases, 5 (cases 16, 22, 23, 24 and 25) were group I, type III; 3 (cases 9, 11 and 18) were group II; 1 (case 10) was group I, uncommon type; 1 (case 13) group I, aberrant type. Strains isolated from cases 5 and 7 were not sent to Dr. Scott, but tests in the laboratory of this hospital showed them to be group I. One strain, case 4, was not tested. It is to be noted that meningitic cases from whom the same agglutinative type was isolated showed widely different premeningitic periods. For instance, cases 16 and 22, from whom group I, type III, strains were obtained, each had a premeningitic period of twelve hours, while cases 24 and 25, from whom the similar group I, type III, strains were obtained, had premeningitic periods of two weeks and seven weeks respectively.

DISCUSSION

The fact that the number of cases of ameningitic meningococcal septicæmia approached the number of meningitic cases in this series strongly supports Heinle's statement that "meningococcic septicæmia can no longer be regarded as a rare disease." The character of the skin lesions, with their sudden occurrence in crops, associated with symptoms of infection, fever and leucocytosis in the presence of proven bacteræmia, provides good evidence that they are due to localisation of organisms in the skin. The isolation by Kennedy (1926) of gram-negative diplococci from what appears to have been a similar lesion is strong confirmation of this view. So, too, the muscle and joint pain, abrupt in onset and often occurring at the same time as the skin lesions in the proven bacteræmic cases, seems to be due to similar localisation of bacteria in deeper tissues. The recovery by Still (1898) of a gram-negative diplococcus from a tendon sheath—the site, apparently, of a similar lesion—is corroborative evidence.

The occurrence of skin lesions, localised muscle pain or localised joint pain during the premeningitic phase of meningitic cases is strong, if not conclusive, evidence that the premeningitic illness was really due to meningococcal septicæmia. More of the ameningitic cases might have developed meningitis, like case 10, had the infection not been interrupted before that incident. The course of the infection as exhibited by the patients in this series as a whole appears to have been the development of bacteræmia followed by localisation of bacteria in the skin, skeletal tissues and sometimes the central nervous system. If the nervous system was not involved early, remissions and relapses occurred and chronic meningococcal septicæmia developed.

In some of the meningitic cases with longer premeningitic periods the diagnosis might well have been made and effectual treatment given before the onset of meningitis This would have resulted in an increase in the number of ameningitic cases in the series, and—what would have had more significance—a corresponding reduction in the number of cases of meningitis treated in this hospital In others with a shorter premeningitic phase appreciation of the significance of such signs and symptoms might have suggested the character of the infection and have led to closer supervision and earlier treatment It is still important that cases of meningococcal meningitis should be treated at the earliest possible moment, further reduction in mortality seems to depend on such early treatment

There is no reason to suppose that a peculiar susceptibility or resistance of the host was operative in this series Some of the patients had recently arrived in this country, others had been here for a year or more There is nothing to suggest that the troops from which they came differed in any way from their fellows, or that the environment in which they lived affected their reaction to the infection The fact that organisms of several different agglutinative types were recovered from both the ameningitic and meningitic groups goes far to exclude the possibility that a special characteristic of the organism was important in determining the course of the infection It appears unlikely, therefore, that the findings here reported are peculiar to this group

SUMMARY

A series of 26 cases of meningococcal infection, occurring in Canadian soldiers stationed in England and admitted to a Canadian general hospital between July, 1940, and June, 1941, is reported

Of these patients, 11 did not have meningitis on admission, but suffered from meningococcal septicæmia, only one of these subsequently developed meningitis The clinical findings in this group include the presence of characteristic skin lesions and of localised muscle pain and joint pain

Most of the 16 meningitic patients had a premeningitic phase in which the signs and symptoms were identical with those of the patients in the ameningitic group, and were no doubt also due to meningococcal septicæmia

PARADOXICAL CEREBRAL EMBOLISM

WITH RECOVERY

ALAN GRAHAM PORTER, M B CAMB
HOUSE PHYSICIAN AT THE EMERGENCY HOSPITAL, CAMBRIDGE

PARADOXICAL embolism, by definition, is the passage of an embolus, usually originating in a thrombus of a systemic vein, direct from the right to the left side of the heart, without traversing the pulmonary vessels, to produce a systemic arterial embolism The condition was first described by Cohnheim (1876), and Zahn (1881) demonstrated an embolus in situ astride a patent foramen ovale Von Recklinghausen (cited by Thompson and Evans 1929–30) suggested the term "paradoxical," rather than "crossed" embolus which had previously been used From an analysis of 13,234 consecutive autopsies, Thompson and Evans found that paradoxical embolism was responsible for death in 4% of all cases of cerebral embolism, and mentioned that diagnosis during life can never be quite certain The following is a case of paradoxical cerebral embolism in which the patient recovered.

A gunner, aged 26, admitted to hospital on March 7, 1941, complaining of pain and swelling behind left knee of 24 hours' duration Had had varicose veins for some years but they had never given trouble Tender and swollen varicose vein behind left knee, diagnosis of phlebitis made and treatment instituted On March 11 thrombosis had spread up great saphenous vein for several inches On evening of the 21st patient was lying on his bed, having been allowed up day or two, and when spoken to was found to be Soon regained consciousness, but speech slurred, both widely dilated and generalised tremor of limbs Next ing complete flaccid left sided hemiplegia, fine left, paralysis of left external rectus oculi, left palate and lower face Incontinence urine, which lasted 24 hours 23rd paralysis had become spastic, with increased reflexes and absent abdominal reflexes on left and left extens plantar response No alteration of sensation or any abnormal sign in central nervous system Lumbar produced normal fluid under normal tension No enlarge ment of heart or cardiac murmurs, blood pressure 125/ Chest showed no evidence of pulmonary embolism Tempera ture and respirations normal X ray of chest at later da normal Urine normal

By March 27 movement returning to left foot and knee, and by end of April patient was moving about ward with help On May 24 examination prior to a medical board revealed slight left sided lower facial weakness, weakness of conver ence of left eye with bilateral nystagmus on looking to left, some weakness of left hand and arm and very slight weakn of left leg and foot, left abdominal reflexes diminished, with accentuation of deep reflexes on left and left extensor plantar response All these signs were less a month later and patient was then walking about freely

DISCUSSION

The embolism had presumably occurred in the right middle cerebral artery, in the region of the internal capsule—the commonest site for such a lesion though Hartfall (1931) recorded a case of paradoxical embolism in the basilar artery
